OPIM639 · Innovations & Operations of Intelligent Online Marketplaces

Chagee: opening overseas stores right

One new store: forecast demand, plan the inventory, choose the counter, review

Group 3

Keziah, Jin, Ayumi, Revan

CONTENTS

Six chapters: one new store, four gates from forecast to review

1	**Context** One new store: the whole-store problem, and what AI would add	slide 1	0:50
2	**Scope** Which course topics we use, which we leave out, and why	slide 2	0:40
3	**Predict** Gate 1: what demand the whole store should plan for	slide 3	0:40
4	**Provision** Gate 2: the opening inventory plan, with fresh milk as the worked example	slides 4 and 5	1:15
5	**Counter** Gate 3: how the counter flows, and which one to install	slides 6 and 7	1:30
6	**Review** Gate 4: review after opening, and the conditional business case	slides 8 and 9	1:50

About 6:55 on stage, then 3:00 for Q&A. Click a chapter to jump to it. Appendix slides are in the handout only.

One new store, no local sales history: estimate demand, plan the inventory, choose a counter, then update

We are opening a store with no local sales history. We need to estimate demand, translate that demand into an inventory plan, choose a counter configuration, and update those decisions after opening.

Why it matters for Chagee

345 overseas stores in 7 markets and about 200 openings planned a year; each commits stock and a counter before local sales exist.

Proposed AI (not built here)

Forecast the whole store's demand from comparable stores, cross-checked by pre-launch app sign-ups, and validate it against actual sales.

What this prototype calculates

Synthetic inputs: a demand range, one inventory worked example (fresh milk) and a counter simulation. Tea, other ingredients and packaging are planned qualitatively. No trained model.

Who decides

People: teams set the inventory plan and choose the counter from these outputs and local constraints.

INTERACTIVE EXPLAINER WHERE AI ENTERS A NEW STORE'S OPENING

Click a step. Today's practice is our reading of public sources and one industry conversation, not a Chagee statement.

1 Members → 2 Forecast → 3 Opening inventory → 4 Counter → 5 After opening

STEP	TODAY (OUR READING)	WHAT AI ADDS	WHO DECIDES · WHERE
1 · Members	Members order through the app (our understanding).	**Read sign-ups and pre-orders as early demand evidence.**	Membership / CRM *slide 3*
2 · Forecast	Judgement-led by a local General Manager (our reading).	**A proposed demand range from member signals, with hype and habit separated by existing-market proxies.**	Market-entry leads and GMs *slide 3*
3 · Opening inventory	Direct, standardised sourcing of tea and milk for domestic stores (company release).	**Turn the forecast into an item-by-item opening list; size fresh milk with newsvendor logic as the worked example.**	Supply chain / planning *slides 4 and 5*
4 · Counter	Moving toward semi-automation: QR-scan dispensing, Chagee Express.	**Simulate the counter before the store exists, and flag which inputs would change the choice.**	Store format / equipment; franchisees *slides 6 and 7*
5 · After opening	Not covered by public sources.	**Compare actual demand with the range to narrow the next market's forecast.**	Market-entry leads *slide 8*

Printed with all five steps shown. Live: click a step to see one at a time.

FOUR GATES

Predict → Provision → Counter → Review.

Scope: the whole store. Each gate states the decision, its evidence, a suggested action, the trade-off and what the model cannot establish. Figures are illustrative assumptions.

SPEAKER NOTES · PAGE 3

Context and problem

About 50 seconds. Start with one store: we are opening a store with no local sales history. We need to estimate demand, translate it into an inventory plan, choose a counter, and update those decisions after opening. Chagee faces that about 200 times a year abroad. The scope is the whole store: demand for every drink, and an inventory plan for tea, fresh milk and alternatives, other ingredients, cups, lids and packaging. Be clear about three layers. The AI we propose would forecast the store's demand from comparable stores, cross-checked by pre-launch sign-ups; it is not built here. This prototype calculates from synthetic, assumed inputs: a demand range, one inventory worked example, fresh milk, and a counter simulation. People make the decisions. The deck walks the four gates: Predict, Provision, Counter, Review.

Sources: Scale facts and planned openings: L-jiemian. Direct sourcing, HQ distribution: L-prn (company release). Semi-automation: L-unsw, L-cyberrt. Kuala Lumpur opening day: L-gabgrowth (secondary). App ordering and GM-led forecasting: I-leeyen (INFORMAL - check with Lee Yen before presenting).

A closed app-to-store channel puts our problem in Topics 3 to 5, not the marketplace topics

INTERACTIVE EXPLAINER EIGHT COURSE TOPICS: CLICK ONE TO SEE WHY IT IS IN OR OUT

TOPIC 1
~~Introduction to Online Retailing~~
OUT
One closed channel, app to store: no online-versus-store trade-off to weigh (our reading).

TOPIC 2
~~Online Marketplaces~~
OUT
No third-party sellers, so no sell-versus-fulfilment-service choice (our reading).

TOPIC 3
Analytics and AI for Online Retailing
IN
→ Predict · slide 3
Predicting a new market's demand from app-member signals.

TOPIC 4
Supply Chain Management using AI and Robotics
IN
→ Provision · Counter
Supply-chain planning turns the forecast into stock; equipment selection sizes the counter.

TOPIC 5
Order Fulfillment for Online Retailing
IN
→ Provision · Counter
Preparing the opening inventory, and work shared by people and robots (the bucket brigade).

TOPIC 6
Last-mile Delivery for Online Retailing
NOT USED
Outside our question, which stops at the counter.

TOPIC 7
Service-oriented platforms
NOT USED
Outside our question.

TOPIC 8
~~Omni-channel Retailing~~
OUT
One channel, so no channel conflict; the franchise revenue share is out of scope.

INTERACTIVE EXPLAINER WHERE DOES UNCERTAINTY LAND?

Why this slice: with sourcing fixed, a demand miss lands in the store, on its opening stock or its counter speed (our reading, not a Chagee statement).

Rigid sourcing | Localised sourcing

Rigid sourcing — Chagee today, our reading		Localised sourcing — For contrast only	
Sourcing ○○○	Fixed: single origin	**Sourcing** ●●○	Flexes with local suppliers
Distribution ○○○	Fixed: run from HQ	**Distribution** ●○○	Shorter, local
Opening stock ●●●	Absorbs the miss	**Opening stock** ●○○	Less exposed
Counter speed ●●●	Absorbs the miss	**Counter speed** ●●●	Still exposed

●○○ low ●●● high exposure to a demand miss

Printed: every tile shows its status and reason; both sourcing columns are shown.

OUR SCOPE

Three topics, three decisions.

Topic 3 feeds Predict; Topics 4 and 5 feed Provision and Counter. Sourcing is fixed by design, so we take it as given, and the franchise revenue share stays out of scope.

Scope: what we left out and why

About 40 seconds. The course has eight topics. Chagee runs one closed channel, from its app to its own stores, so the marketplace topics do not arise: there are no third-party sellers, no fulfilment-service choice and no channel conflict. Topics 6 and 7 are simply outside our question, which stops at the counter. Topics 3, 4 and 5 are where a new store's risk sits: predicting demand, planning the opening inventory, and choosing people or robots at the counter. Use the toggle: because Chagee's sourcing is fixed, a demand miss can only be absorbed in the store. If asked why, open How the logic works: goods flow from suppliers through warehouses to stores, and a miss is absorbed wherever something can still change in time; with origin and routes fixed long before opening, only the store's opening stock and counter speed can react. That is why we chose this slice.

Sources: Topic names and content: OPIM639 course outline (AY2026-27), weekly lesson plans. Closed channel, no third-party sellers: brief.md section 3, our reading; app ordering rests on I-leeyen (INFORMAL). Direct sourcing and HQ distribution: L-prn. Franchise revenue share: out of scope, no figure claimed.

Predict: plan on a demand range, not one number, and treat the range as an assumption to test

GATE 1 · PREDICT

DECISION
What demand should the whole store's inventory and counter planning assume?

SUGGESTED ACTION
Plan on about 3,889 cups a week, within an illustrative 80% range of 2,625 to 5,153; treat it as an assumption to test.

EVIDENCE
Base **3,889 cups/week** 80% range **2,625–5,153**
Half-width **±32.5%**

TRADE-OFF
Plan too low: stockouts, queues and lost sales. Plan too high: stock that expires or ties up cash, and machines or staff that sit idle.

LIMITATION
The range is assumed, not calibrated, and demand can fall outside it. It cannot approve a site or show that a store is viable.

Demand prediction `COURSE CONCEPT · TOPIC 3`
`PROTOTYPE: AN ASSUMED RANGE, NO TRAINED FORECAST` Estimate how much customers will buy, as a range rather than one number. *Informs: the whole store's inventory and counter planning*

Proposed AI: comparable stores first, sign-ups as a cross-check

A model trained on Chagee's existing stores would set the base; app sign-ups would cross-check it. Not built here: our base is assumed.

A narrower range is an assumption to test

The slider narrows it from ±50% to ±15% by assumption; no evidence yet that member data does this.

Hype versus habit needs a proxy

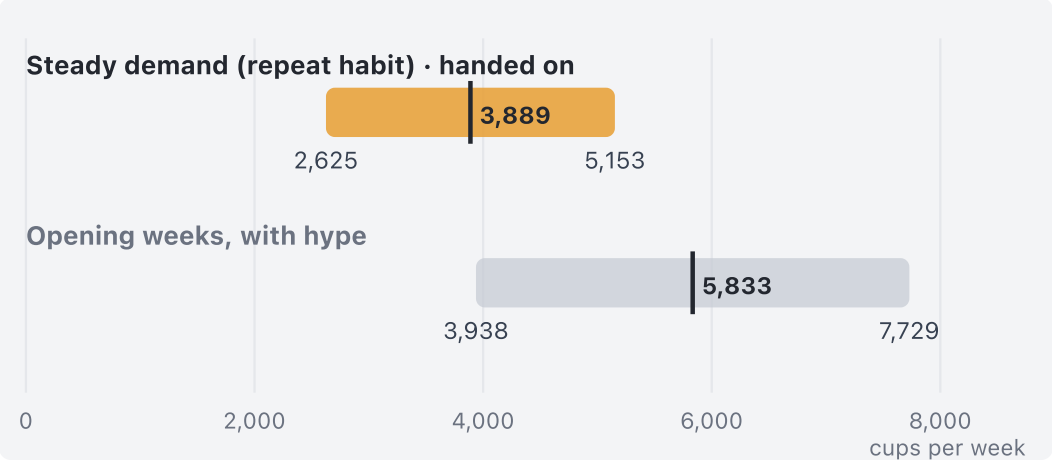

No repeat history yet: use repeat rates in existing markets or nearby stores. Kuala Lumpur reportedly sold 1,000+ cups on day one (secondary).

Blind spot: tourists and non-app orders

They sit outside the member signal, so the range runs low where tourists matter.

INTERACTIVE EXPLAINER DEMAND RANGE BEFORE OPENING: A SENSITIVITY

Weekly cups at one new store. The bar is an illustrative 80% demand range: we assume about that share of outcomes falls inside it.

Assumed signal strength 50% → ±32.5%

Opening hype removed | Hype included

Plan on about 3,889 cups a week of steady demand (opening hype removed). Illustrative 80% demand range: 2,625 to 5,153. The range is assumed, not calibrated; demand can fall outside it.

Printed at the default assumed signal strength (50%) with opening hype removed.

WHAT THE RANGE IS FOR

Low end (2,625)
Risk of excess stock (perishables expire) and unused capacity.

High end (5,153)
Risk of shortages, queues and lost sales.

Provision turns the range into the opening inventory list; fresh milk adds shortage and waste costs.

Counter uses demand, uncertainty and local wages and machine costs together.

Not in the signal: tourists and non-app orders.

Predict

About 40 seconds; under time pressure, read only the gate card. Chagee orders go through the app (our understanding, to be confirmed), so a pre-launch waitlist could be read as a demand signal. Be clear what the slider is: we assumed that more signal narrows the band, along a straight line between two end points; we have not shown member data does that. Separating opening hype from repeat habit also needs a proxy, because a new store has no repeat history: repeat rates in Chagee's existing overseas markets, nearby stores, or waitlist members who already order elsewhere. So this is a method to back-test on past openings. Gate card: does the band change the counter? Barely: mixed overtakes all-human only beyond about ±57%. The range matters most for the inventory plan, next.

Sources: App-only ordering with tourist exceptions: I-leeyen (INFORMAL - check before presenting). Kuala Lumpur opening day: L-gabgrowth (secondary). Existing overseas markets: L-jiemian (7 markets). Not novel - AI forecasting and siting: L-starbucks. Band narrowing with signal: assumption (predict.signal_strength_default, demand.uncertainty_no_signal / _strong_signal). Trigger: sim/ breakEven over the band half-width, default volume, moderate surge.

Provision: translate the sales forecast into an opening inventory plan

GATE 2 · PROVISION

DECISION
What must be on hand on opening day, what should the first delivery bring, and what is replenished later?

SUGGESTED ACTION
Build the opening list item by item from the demand range: tea, milk and alternatives, other ingredients, cups, lids and packaging. Size fresh milk with the worked example.

EVIDENCE
Quantified here **`fresh milk only (slide 5)`**
Needs Chagee data **`menu mix · recipes · lead times · minimum orders`**

TRADE-OFF
Too little of any one item stops sales. Too much ties up cash and storage, and perishables expire or lose quality.

LIMITATION
No quantities for tea, other ingredients or packaging: their inputs are not in our sources. Inventory and counter are not optimised together.

FROM FORECAST TO PURCHASE ORDER

1. **Forecast cups**
   The whole store's weekly range (slide 3). Cups alone are not enough: drinks use different ingredients.
2. **Product mix**
   Share of each drink and format (size, hot or cold). Requires menu-mix data.
3. **Recipes and materials**
   Ingredient requirement = forecast drink quantities × ingredient amount per drink. Packaging follows orders and formats.
4. **Deliveries and stock**
   The order nets off usable stock and deliveries due, adds expected losses, and fits lead times, shelf life, storage and supplier minimums.

Preparing inventory for fulfilment
`COURSE CONCEPT · TOPIC 5` `PROTOTYPE: FRESH MILK ONLY`
Have every material on hand before the orders arrive, item by item. *Informs: what must be on hand on opening day*

Lead time `EXPLAINED, NOT MODELLED` The time from placing an order to having it usable in the store. *Informs: how early each item is ordered*

Reorder point and safety stock `EXPLAINED, NOT MODELLED` Reorder when stock falls to the usage expected during the lead time, plus a buffer for demand above it. *Informs: when each item is replenished*

OPENING PLAN BY CATEGORY: QUALITATIVE, NO QUANTITIES

ITEM	WHAT DRIVES ITS DEMAND	MAIN CONSTRAINT	OPENING DECISION	REPLENISHMENT	NEEDED FOR A NUMBER
Tea leaves	Tea drinks in the mix × tea per drink	Sourcing lead time, minimum orders, storage; quality fades with age and handling, so tea also has waste and quality risk	How much to hold before opening: the opening weeks plus the time a reorder takes to arrive	Reorder when stock reaches usage over the lead time plus a buffer	Recipes · supplier lead time · minimum order · usable life
Fresh milk and alternatives	Milk drinks × milk per drink; alternatives by customer choice	Short shelf life, chilled space, delivery frequency	First fresh-milk delivery: the worked example (slide 5)	Each delivery sized on actual sales	Recipes · share of alternative milks · delivery schedule
Other ingredients	Each recipe's amounts	Each has its own shelf life and supplier terms	Plan per recipe and shelf life: perishables like milk, longer-life items like tea	Per item's usage and lead time	Menu recipes · shelf lives · supplier terms
Cups, lids, seals, packaging	Orders by format	Lead time, minimum orders, bulky storage	Cover opening demand plus the reorder lead time: no cup or seal, no sale, even with ingredients ready	Reorder on usage and lead time	Format mix · supplier lead time · storage space

Origin (imported or local) is not public for overseas stores: Chagee's direct sourcing of tea and milk is documented for its domestic operations (L-prn). Quantities, lead times, shelf lives and service levels are not in our sources, so none are shown.

MATERIALS AND CAPACITY

A forecast becomes sales only if the store has both materials and service capacity.

Enough milk is not enough if tea or cups run out. Enough ingredients are not enough if the counter cannot serve customers (slides 6 and 7). Both use the Predict range; the prototype does not optimise them together.

Provision

About 40 seconds. Predict gives us cups for the whole store, but cups alone do not tell us what to buy: different drinks use different ingredients. So the plan runs from forecast cups, to the product mix, to recipes, to deliveries. Ingredient requirement is forecast drinks times the amount per drink; the purchase order then nets off stock on hand and deliveries already due, adds expected losses, and fits supplier minimums. The table goes item by item. Tea keeps longer than milk, but it still has lead times, minimum orders and quality that fades, so it is not risk-free. Milk is perishable: that is our worked example, next. Packaging is easy to forget: no cup or seal, no sale. We show no quantities: recipes, menu mix, lead times and minimum orders are not in our sources. And materials are only half: enough ingredients are not enough if the counter cannot serve customers.

Sources: Direct sourcing of tea and milk, domestic operations: L-prn (company release); overseas origin not claimed. Demand range: the Predict model (assumptions.json, illustrative). Every other cell: our qualitative planning logic, no Chagee figure.

Worked example: choosing the first fresh-milk delivery

The whole-store plan includes many materials. We use fresh milk to demonstrate the ordering trade-off because unused stock can expire quickly.

GATE 2 · PROVISION · FRESH MILK

DECISION

How much fresh milk should the first delivery bring?

SUGGESTED ACTION

Steady demand: about 788 L for the first 7 days. If the expected opening surge is real, about 1,182 L: this delivery falls inside it.

EVIDENCE

Short vs waste, per L **S$25.47 vs S$2.55**

Order covers **91% of outcomes** Expected waste **209 L**

Expected shortage **42 cups**

TRADE-OFF

Order less: more missed cups at S$3.82 each. Order more: more milk thrown away at S$2.55 a litre. A shortage costs more, so the order sits above base demand.

LIMITATION

Sizes one delivery of one item; it does not optimise the whole inventory. Still runs short in about 9% of outcomes. Generic milk costs, one amount per cup.

Newsvendor logic `IMPLEMENTED FOR FRESH MILK` Choose the order quantity by balancing the cost of unused stock against the cost of running short. *Informs: the size of the first fresh-milk delivery*

Decision and method

How much milk should the first delivery bring? Newsvendor logic balances the cost of leftover stock against the cost of running short.

Inputs

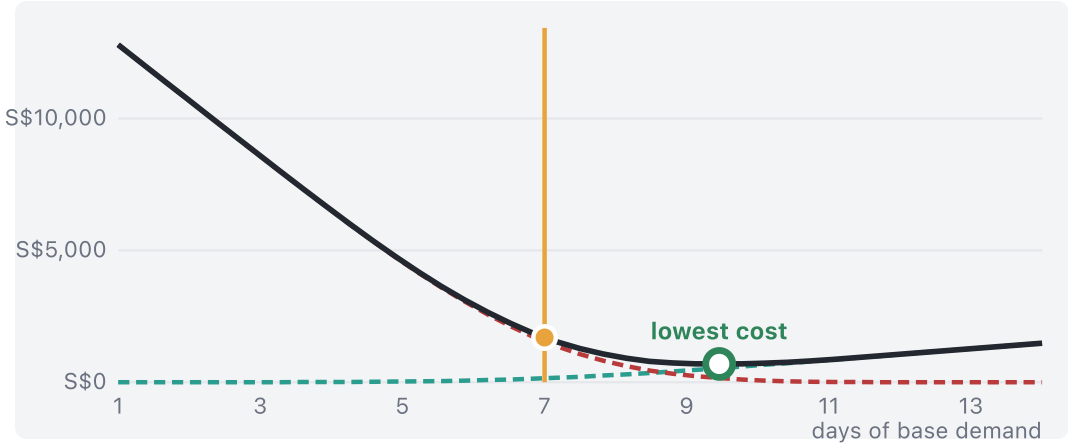

The demand range from slide 3; a missed cup costs S$3.82, a wasted litre S$2.55; shelf life about 7 days. Simplification: every cup uses 0.15 L; real recipes differ.

Opening surge or steady demand

The surge is assumed to last 2 weeks, so this delivery falls inside it: about 1,182 L if the surge is real, 788 L on steady demand.

INTERACTIVE EXPLAINER **FIRST FRESH-MILK DELIVERY CALCULATOR**

Expected cost of the first delivery at one store, using the range from slide 3. Milk costs are generic: overseas sourcing is not public.

Days of opening stock 7 days

Order about 788 L for the first 7 days, using steady demand (opening hype removed). That is 9.5 days of base demand, just above the top of the range (top of range 9.3 days).

This delivery falls inside the assumed 2-week opening surge (×1.5): if the surge is real, order about 1,182 L, or include it on slide 3.

AT 7 DAYS OF STOCK

S$1,695 expected

Milk wasted **S$149**

Cups missed **S$1,546**

BEST ORDER AT THIS BAND (±32.5%)

9.5 days **S$694**

Same order, strong signal **S$320**

Hand-off: fresh milk is one line of the opening list (slide 4). The counter is decided by volume and input costs, not this band (slide 7).

Printed at the band from slide 3 (opening hype removed) and the default of 7 days of stock.

SPEAKER NOTES · PAGE 7

Provision · worked example

About 35 seconds; under time pressure, read only the gate card. The whole-store plan includes many materials; we use fresh milk to show the ordering trade-off because unused milk expires quickly. Newsvendor logic balances the cost of leftover stock against the cost of running short. A missed cup costs far more than a wasted litre, so the best order sits above the base forecast. Be clear about the opening surge: we assume it lasts 2 weeks, longer than this delivery, so if it is real the order is about 1,182 L, not the 788 L steady demand gives. Limits: one item, one delivery, one milk amount per cup, generic costs.

Sources: All figures: assumptions.json (illustrative). Best order: sim/ provision at the Predict range; the surge order is the same optimum in days of demand applied to opening-week demand. Milk trigger: sim/ milkTrigger. Overseas milk sourcing: unknown, deliberately not claimed (brief.md section 9).

Counter flow: people pass work along like a bucket brigade; machines are fixed, so they queue at the bottleneck or sit idle

Bucket brigade `COURSE CONCEPT · TOPIC 5` `ILLUSTRATION WITH THE WEEK 5 RULES` Workers pass each order along a line and rebalance themselves, slowest first. *Informs: how much a crew absorbs in a surge*

Bottleneck `COURSE CONCEPT · TOPIC 5` `ILLUSTRATION AND COST MODEL` The slowest step sets the pace of the whole line. *Informs: where a fixed machine line queues*

People pass the work along

Each worker carries a drink downstream and hands it over. In a surge the handover point moves, so the load evens out: one way a crew shares work.

Machines stay at their station

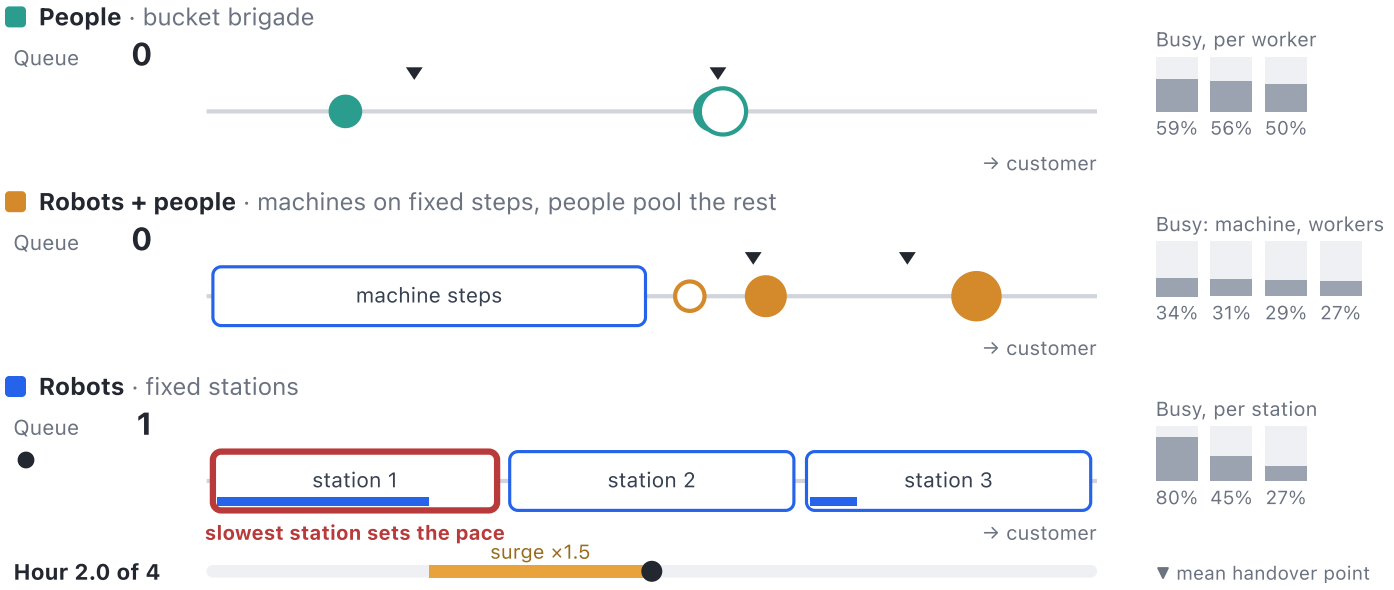

A fixed station cannot hand work back or take on more. The queue builds at the slowest one, wherever it sits on the line.

Faster in the peak, idle at low volume

Machines can cut the wait in a surge, but sized for the peak they are busy only part of the day, and idle capacity is what a store pays for.

INTERACTIVE EXPLAINER COUNTER FLOW: PEOPLE AND MACHINES IN A SURGE

Movement illustration in Week 5 units: not a cost model, not measured times. More detail: appendix A5.

Moderate ×1.5 surge, 4-hour run	Machines matched to crew		As sized in cost model	
	Peak queue	Busy (range)	Peak queue	Busy (range)
People	0	57%–66%	0	57%–66%
Robots + people	0	28%–32%	0	10%–33%
Robots	2	38%–90%	1	19%–40%

Printed at the end of the surge window; the table compares both sizing settings over the full run.

OUR VIEW

Materials are half of opening; service capacity is the other half.

People flex; machines come in whole units. So the counter choice turns on volume and local costs: next slide.

Counter

About 40 seconds. Materials are only half of an opening; the counter is the other half. Press play. Top lane: people work as a bucket brigade, a course concept: each carries a drink along and hands it over, so when the surge hits the load evens out. Bottom lane: machines are fixed at their station, so the queue builds at the slowest one: the bottleneck. Flip to as sized in our cost model: the machines stop queuing, but sit idle much of the run, and idle capacity is what a store pays for. This is one mechanism, in the Week 5 units, not measured times; the worker-order comparison and time to serve are in appendix A5. Next: what each counter costs.

Sources: Bucket-brigade engine: course Week 5 explainer (reference, read-only), wrapped by sim/mechanism.js. As-sized ratios read from sim/ peakUtilisation and plan. Illustration settings: assumptions.json illustration (mixed_sizing needs approval).

Counter: at our inputs all-human and mixed are S$0.02 a cup apart, so choose with all inputs together

GATE 3 · COUNTER

DECISION

Which counter should this store install: all-human, mixed, or full automation?

SUGGESTED ACTION

At 556 cups a day all-human is cheaper by S$0.02 a cup: close, but above the S$0.01 tie line. Choose using all current inputs together.

EVIDENCE

Cost per cup **all-human S$0.65 · mixed S$0.66 · all-robot S$0.91**

All-robot machines busy **21% of open hours**

TRADE-OFF

All-human: cheapest here, but depends on trained staff. Machines: faster in the peak, but idle and costly when volume is low.

LIMITATION

Small gap on a simplified staffing model that misses its Week 5 check (4.7% and 6.8% against ±3%). No measured service times: a candidate to test in a pilot, not an instruction to install.

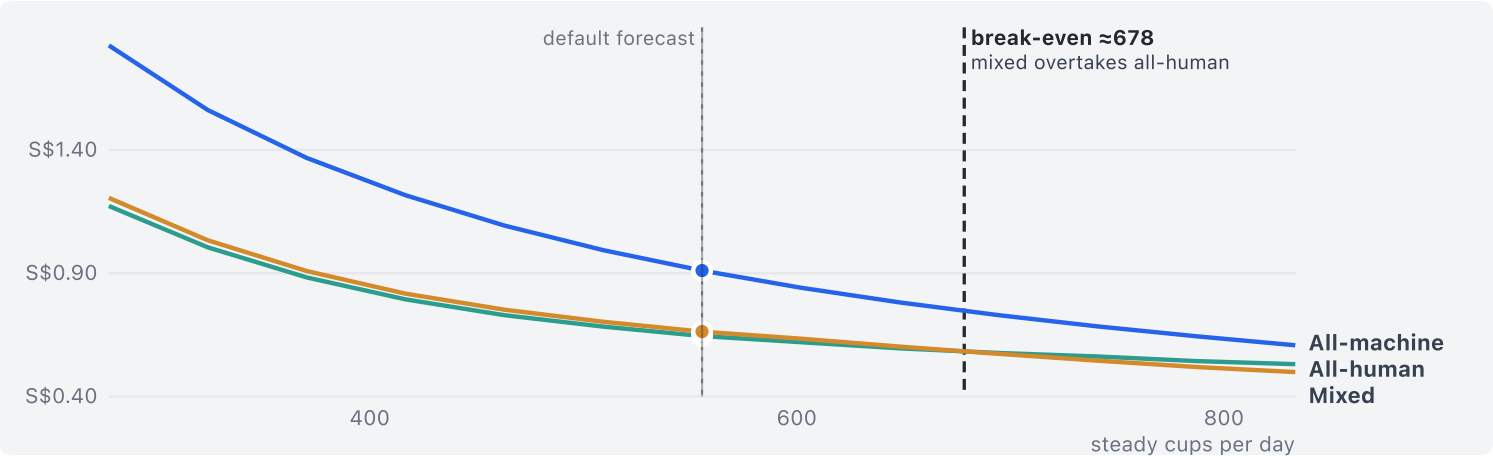

INTERACTIVE EXPLAINER COST PER CUP, BY COUNTER

Faster service does not mean a lower cost per cup: at low volume, machine capacity sits unused. Labour, machines and lost sales per cup served, by steady volume.

Capacity utilisation `IN THE COST MODEL` The share of available capacity that is actually used. *Informs: why idle machines raise the cost per cup*

Selecting robotics equipment `COURSE CONCEPT · TOPIC 4` `COMPARED IN THE COST MODEL` Choose automation that fits the volume and the work, not the most automation. *Informs: which counter to install*

All-human Mixed All-machine

All-human	Mixed	All-machine
S$0.65	**S$0.66**	**S$0.91**
cheapest	+S$0.02	+S$0.27

At 556 cups/day. All-robot machines are busy 21% of open hours.

Printed at the default forecast.

ONE-VARIABLE THRESHOLDS: WHICH ASSUMPTIONS DESERVE A CLOSER LOOK

MIXED WINS WHEN…	IS	OURS	GAP
Machine cost	below **S$1,800/month**	S$1,909/month	-6%
All-human coordination	below **0.85**	0.90	-6%
Wage per hour	above **S$15.97/h**	S$15.06/h	+6%
Mixed coordination	above **0.98**	0.90	+9%
Steady volume	above **678 cups/day**	556 cups/day	+22%
Forecast band	above **±57%**	±32.5%	+75%
New-hire share	none in 0% new staff to 50% new staff: all-human cheaper throughout		
Machine time	none in 0.70× to 2.00×: all-human cheaper throughout		

Each row moves one input with the rest at our defaults; nearest first. A crossed row is a reason to recheck, not a rule to switch.

How sure are we? A close call. The gap is S$0.02 a cup. Our staffing shortcut misses its Week 5 check (4.7% and 6.8% against ±3%), and with walking modelled people reach only 90% of the assumed capacity (70% at today's counter). Test the ranking with real staffing data before relying on it.

Counter

About 45 seconds; under time pressure, read only the gate card. Speed has a price. The chart is the cost model: labour, machines and lost sales per cup against steady cups per day. At our forecast of about 556 cups a day all-human is cheaper, but only by S$0.02 a cup, so we do not recommend a default. The table says when mixed wins instead, nearest first: machine cost below about S$1,800 a month, all-human staff coordinating a little worse than we assume (below 0.85), or a wage above about S$15.97 an hour; each is only a few per cent away. Volume needs about 678 cups a day. Full automation needs about 1,820. And be clear how sure we are: it is a close call on a simplified staffing model, so it is a candidate to test in a pilot, not an instruction to install equipment.

Sources: Wage S$ per hour worked, fully loaded: L-mom-pwm, L-mom-ows, L-cpf, L-sdl, L-mom-leave, L-mom-ph. Costs and break-evens: sim/ cost model and breakEven over cups per day (data.json volumeCurve, breakEven), default band, moderate surge. All inputs: assumptions.json (illustrative).

Review: rerun the comparison with observed inputs and compare it with the original plan

GATE 4 · REVIEW

DECISION
After real sales arrive, does the plan still hold?

SUGGESTED ACTION
Create an updated scenario using observed inputs and compare it with the original plan (All-human by S$0.02 a cup).

EVIDENCE
Feeds the model **steady sales · wage · machine quote · milk costs**
Check by hand **service times · lost orders · waste and stockouts of every item vs plan**

TRADE-OFF
Change too early and you chase the opening hype; change too late and the store keeps the wrong stock or counter.

LIMITATION
Rerunning the model does not validate it, and a new result does not by itself prove that machines should be added.

TRIGGER	FLIPS WHEN	OURS	GAP
Counter: when mixed beats all-human · Store format / equipment, with franchisees			
Machine cost	below **S$1,800/month**	S$1,909/month	-6%
All-human coordination	below **0.85**	0.90	-6%
Wage per hour	above **S$15.97/h**	S$15.06/h	+6%
Mixed coordination	above **0.98**	0.90	+9%
Steady volume	above **678 cups/day**	556 cups/day	+22%
Forecast band	above **±57%**	±32.5%	+75%
New-hire share, Machine time	no threshold in the tested range: all-human stays cheaper throughout		
Counter: when full automation beats mixed · Store format / equipment, with franchisees			
Steady volume	above **1,820 cups/day** · step	556 cups/day	+228%
Wage per hour, Machine cost, Forecast band, Machine time	no threshold in the tested range: mixed stays cheaper throughout		
Fresh milk: when to order at or below the base forecast · Supply chain / planning			
Milk waste per litre	none in S$1.27 to S$5.09/L: order above base throughout (flips at S$25.47/L = S$3.82 per lost cup ÷ 0.15 L)		

One input at a time, the rest at our defaults; nearest first. Thresholds flag what to recheck, not when to switch (slide 7).

INTERACTIVE EXPLAINER UPDATED SCENARIO VERSUS THE ORIGINAL PLAN

Enter observed inputs. Verdict: the full cost model; under S$0.01 a cup is a tie. Nearest threshold: a live estimate.

Wage per hour		S$15.06
Machine cost, per unit per month		S$1,909
Expected steady cups per day		556
Forecast band (±)		±32.5%
Milk waste cost per litre		S$2.55

Original plan: All-human by S$0.02 a cup. **Updated scenario:** same inputs as the plan.

COUNTER **All-human** cheaper than Mixed by S$0.02 a cup

All-human **S$0.65** Mixed **S$0.66** All-machine **S$0.91**

Nearest threshold (live estimate): Mixed would be cheaper if machine cost, per unit per month falls to about **S$1,783** (7% away).

Fresh milk: order above the base forecast (best order at the 91% point of demand); flips only if waste costs over S$25.47 a litre.

Printed at our default inputs.

Decide

About 50 seconds. This is the call to action. There is no default counter; the table collects every trigger from the simulator, nearest first. For mixed over all-human, three sit within a few per cent of our defaults: machine cost, how well staff coordinate, and the wage. Volume needs about 678 cups a day. Full automation needs about 1,820 cups a day, and nothing else in range gets it there. Fresh milk: order above the base forecast unless waste costs over S$25.47 a litre, far outside our range; check stockouts of every other item against the opening list. On the right, put in a market: say a higher wage, or a cheaper machine. The panel recomputes the verdict, how much it wins by, and which trigger is closest to flipping it. If the margin is under a cent a cup, call it a tie and decide on other grounds.

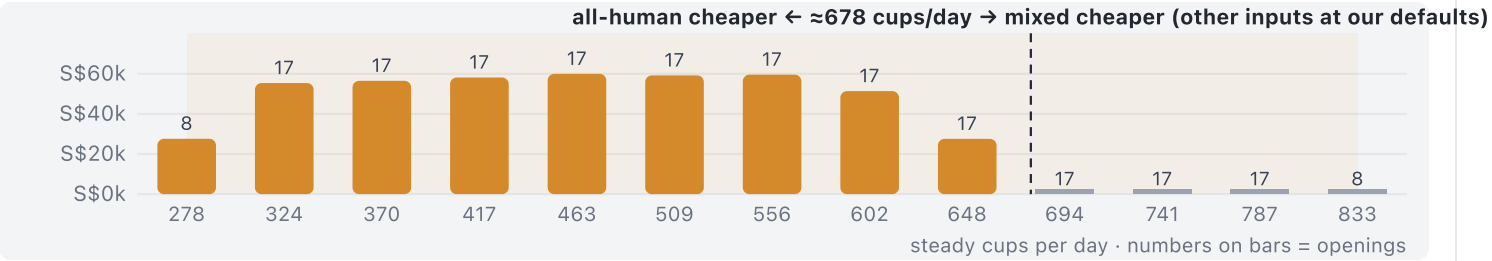

Sources: Wage: L-mom-pwm, L-mom-ows, L-cpf, L-sdl, L-mom-leave, L-mom-ph. Triggers: sim/ breakEven (data.json breakEven, leverNow) and milkTrigger. Your market: sim/ runPoint with simulation.live_draws, nearest flip found by bisection at the user's inputs. All inputs: assumptions.json (illustrative).

Each opening gets a demand estimate, an inventory plan, a counter tested on local costs and a review; only counter and fresh-milk benefits are quantified

INTERACTIVE EXPLAINER WHAT CHOOSING PER STORE IS WORTH (QUANTIFIED PART ONLY)

Comparison: a mixed counter at every opening versus choosing each store's counter for its modelled conditions. The quantified inventory benefit currently covers the fresh-milk example only. Benefits for tea, other ingredients, and packaging have not been estimated.

Bar = openings at that volume × the standard's yearly cost above the cheapest counter (our defaults).

Overseas openings a year		200
Expected steady volume: lowest		278 cups/day
Expected steady volume: highest		833 cups/day

RECURRING · COUNTER COSTS
S$455k
a year, for one year's openings

ONE-TIME · FRESH-MILK STOCK
S$74k
once; other inventory not estimated

142 of 200 openings sit where all-human is cheaper → S$455k a year; **S$370** per opening × 200 → S$74k once

Stock term: fresh milk only, and only if the pre-launch signal works as assumed (slide 3). A fully automated standard would cost S$32,724–S$65,190 more per store a year.

Printed at our defaults: openings spread evenly over our volume range.

FOUR OUTPUTS FOR EACH OPENING

1. **Before committing the site** · Predict `slide 3`
   A demand estimate for the whole store: a range to test, back-tested on past openings.
   Market-entry leads · Membership / CRM
2. **Before the first order** · Provision `slide 4`
   An opening inventory and replenishment plan, item by item; fresh milk sized with newsvendor logic.
   Supply chain / planning
3. **Before fit-out** · Counter `slide 7`
   A counter compared on demand and local costs, all inputs together; a candidate to pilot.
   Store format & franchisee
4. **After opening** · Review `slide 8`
   Compare sales, stockouts, waste and service with the plan; rerun with observed inputs.
   Store operations · Market-entry leads

FINDING

In the tested model, uncertainty did not determine the counter choice.

Volume and operating costs mattered more; demand uncertainty still matters for inventory. This holds for the scenarios we tested, not as a general rule. Next: replace the assumptions with Chagee data and back-test on recent openings such as Korea (Q2 2026).

RISKS AND HOW WE WOULD MANAGE THEM

Staff dependence and turnover
Keep SOP training and flexible roles.

Opening crowds read as steady demand
Decide the counter on steady volume, after the hype.

Tourist and non-app demand is invisible
Widen the band in tourist areas; log walk-ups.

Automation versus the premium teahouse
Keep people at finishing and hand-over.

Conclusion, benefit, next step

About 1 minute. To close: for each opening the four gates give four outputs. A demand estimate for the whole store. An opening inventory and replenishment plan, item by item, with fresh milk worked through. A counter evaluated against demand and local costs. And a review once sales, stockouts, waste and service performance come in. What is it worth? Only part is quantified. Choosing each store's counter, rather than a mixed counter everywhere, is worth about S$455k a year in counter costs across about 200 openings: move the openings and the volume range and the bars follow. The only inventory benefit we quantified is fresh milk, about S$74k once, and only if the pre-launch signal narrows the range as assumed. Tea, other ingredients and packaging have not been estimated. These are modelled avoided costs, not demonstrated savings; appendix A4 sets them against the cost of building the gates. Close on the next step: real data, a back-test on recent openings such as Korea, and a paired pilot.

Sources: Overseas openings planned for 2026 and Korea launch: L-jiemian. Semi-automated counter as Chagee's standard: L-unsw, L-cyberrt (our reading). Per-store cost: data.json volumeCurve and the cups-per-day break-even, x open days. Share below the trigger: openings assumed evenly spread over the approved cups range (illustrative). Stock term: fresh milk only, provision best-order cost, no signal minus default band. Everything else: assumptions.json and sim/ (illustrative).

Sources: assumptions.json.

The model is stable across seeds but misses its Week 5 check, and a handful of inputs decide all-human versus mixed

Week 5 check: pooled staffing formula vs the Week 5 engine

WORKER SPEEDS	ENGINE, LINES/H	POOLED	GAP
1, 1.5, 2	4.300	4.500	**4.65%**
1, 2, 3	5.620	6.000	**6.76%**

Fails the pre-registered ±3% tolerance: the pooled formula overstates a real bucket brigade. The coordination factor (0.9) absorbs part of this.

Seed stability

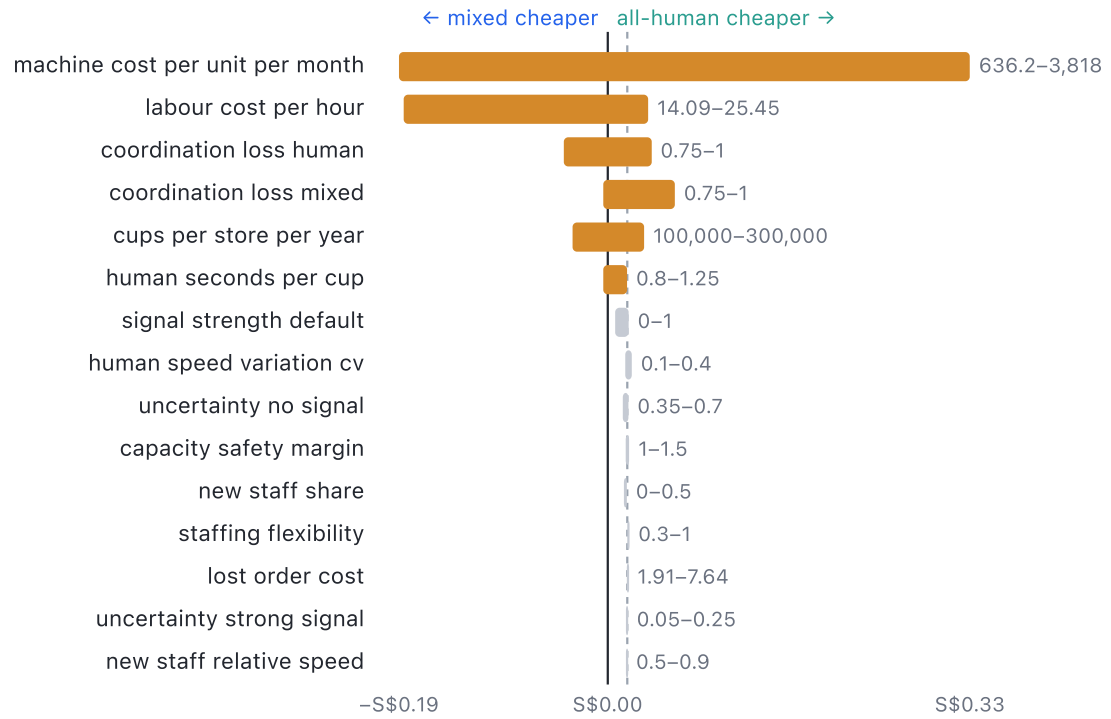

Uncertainty sweep at the moderate surge: 20 of 20 seeds: mixed cheaper than full automation at every band width. The result agrees in every seed. The pre-registered rule asks for a crossover point in most seeds; with none in any seed, the deck shows no crossover point, as the rule requires.

Store replica (walking modelled) vs cost-model capacity, cups per minute

COUNTER	REPLICA	COST MODEL	SHARE
all-human	1.50	1.67	90%
mixed	1.17	1.67	70%
all-machine	3.98	4.00	100%

The replica animates movement only; times and costs on the slides come from the cost model.

Sensitivity: mixed minus all-human cost per cup, one assumption at a time

Dashed: our default gap (S$0.018 a cup, all-human cheaper). Amber bars cross zero inside their approved range, so they can flip the choice; labels show the range tested. No visible effect: target wait minutes, worker speed spread, machine seconds per cup, opening hype multiplier, opening hype weeks, all machine attendant per open hour, milk litres per cup, milk waste cost per litre, milk shelf life days, stockout cost per cup, opening stock days, overseas stores per year.

Appendix A2 · model and validation

Handout only. Week 5 comparison and seed stability from sim/ tests and precompute; the sensitivity chart varies one ranged assumption at a time across its approved range.

Sources: sim/precompute.js: the Week 5 comparison, seed stability, the sensitivity sweep and replica capacity (data.json).

At a new store's volume, a mixed people-and-machine counter beats full automation, because machines sit idle, not because demand is uncertain

We tested the hypothesis that mixed wins only until demand becomes predictable. Our simulator rejected the uncertainty part.

Machines come in whole units, so they sit idle

Even one machine per station serves about 240 cups an hour against a forecast peak of about 61. The fully automated line is busy only 21% to 22% of open hours.

People flex; machines cannot be returned

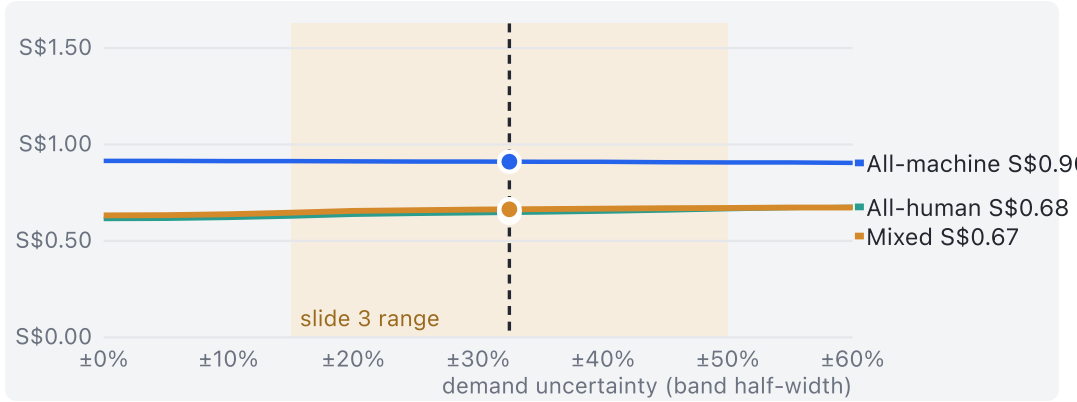

Rosters follow the hour and the real demand, and staff rebalance across stations like a bucket brigade. A mixed counter buys 3 machines instead of 6, with similar staff hours.

Where machines still win

Big surges: at a 2.5× peak, people-based counters lose about 11% of orders and full automation is cheaper. Also steady high volume, consistency and labour scarcity.

INTERACTIVE EXPLAINER COST PER CUP BY COUNTER SETUP

None ×1 surge | **Moderate ×1.5 surge** | Large ×2.5 surge

No crossover: mixed is cheaper than full automation at every uncertainty level shown.

Demand uncertainty ±32.5%

COST PER CUP AT ±32.5%

All-human	S$0.65
Mixed	S$0.66
All-machine	S$0.91
Mixed – machine	−S$0.25

WHAT THE COST IS MADE OF

Automated line busy	21%
Orders lost: mixed	1.3%

What could shift the balance

Machine cost per month	Low S$636	**Default**	High S$3,818	→ mixed cheaper everywhere
Staff turnover (share new)	Low 0%	**Default**	High 50%	→ mixed cheaper everywhere
Forecast narrows (slide 3 band)	No signal ±50%	**Slide 3**	Strong ±15%	

Printed at the default band (±32.5%) and moderate surge.

OUR VIEW

Uncertainty did not decide the counter; volume, wage and machine cost do.

All-human (S$0.65) and mixed (S$0.66 per cup at the default band) are a close call settled by the triggers on slide 7. Machine breakdowns are not modelled, which flatters automation.

Appendix A2 · the uncertainty sweep

Handout only (appendix). Our starting hypothesis was that a mixed counter beats full automation until demand becomes predictable. The simulator only half supports it. Mixed does beat full automation at the default settings, at every level of uncertainty, but the reason is not uncertainty: machines come in whole units, so the automated line sits idle and its fixed cost is spread over too few cups. The uncertainty slider barely moves the lines; a large surge does, and there full automation wins. All-human versus mixed is a close call decided by volume, wage and machine cost (slide 7). Limits: the pooled staffing formula overstates a real bucket brigade (our Week 5 check missed its tolerance, gap 4.7 to 6.8 percent), and breakdowns are not modelled.

Sources: All figures: sim/ with assumptions.json (illustrative). Semi-automation context: L-unsw, L-cyberrt. Not novel - beverage automation: L-gongcha (company-reported), L-slate; store digital twins: L-mosimtec. Labour cost floor: L-mom-pwm, L-cpf.

Claims we did not make

- That Chagee is first at anything, or that anything is not available in the market.
- Any revenue-mix share for franchise supply: sources conflict.
- Overseas milk sourcing details: unknown, so milk costs are generic.
- A Supply Chain Security Act local-sourcing rule: low-quality source.
- Any Chagee internal cost, forecast method or automation plan not in the ledger.
- Measured serve times: every time on the store-replica slide is modelled; the observed row is empty.
- That member data narrows the forecast band: the narrowing is our assumption, tested as a sensitivity.
- That all-human or mixed is proven cheaper: the gap is small and rests on a simplified staffing model.
- A saving against today's practice: the benefit is a modelled avoided cost against a standard counter.
- Anything about menu prices: that would need a demand-elasticity assumption we do not have.
- The informal sub-one-minute fulfilment target from the industry call: not used.
- That the prototype contains a trained AI model: it calculates from synthetic, assumed inputs.
- That rerunning the model with observed inputs validates it, or proves machines should be added.
- That uncertainty never matters for the counter: the finding holds for the scenarios we tested.
- Sales revenue or a payback for Chagee: A4 sets modelled avoided cost against approved but illustrative costs.
- Quantities, lead times, shelf lives, minimum orders or origin for tea, other ingredients or packaging.
- Inventory savings beyond fresh milk: tea, other ingredients and packaging have not been estimated.
- That inventory and counter are optimised together: the prototype treats them separately.

Appendix A3 · sources and claims not made

Handout only. Ledger from assumptions.json _sources; the list of claims not made follows brief.md section 9 plus the limits found while building the deck.

Sources: assumptions.json _sources; brief.md section 9.

Over 5 years the modelled savings cover the cost of building and running the gates in year 5, leaving about S$289k ahead (illustrative)

ITEM	YEAR 1	YEAR 2	YEAR 3	YEAR 4	YEAR 5	ASSUMPTION / HOW CALCULATED
Benefit: modelled avoided cost (no sales revenue)						
New stores opened	200	200	200	200	200	About 200 overseas openings planned for 2026 (L-jiemian); held flat after that (no later figure in our sources)
Store-years using the gates	100	300	500	700	900	Earlier stores trade all year; new stores 50% of a year (mid-year openings)
Counter saving (recurring)	S$228k	S$683k	S$1,138k	S$1,594k	S$2,049k	Store-years × S$2,277: the mixed counter's yearly cost above the cheapest counter, openings spread over our volume range (slide 9)
Fresh-milk opening stock (once per opening)	S$74k	S$74k	S$74k	S$74k	S$74k	Openings × S$370: best milk order with no signal minus with the member signal; if the signal narrows the range as assumed. Tea, other ingredients and packaging: not estimated
Total benefit	**S$302k**	**S$757k**	**S$1,213k**	**S$1,668k**	**S$2,123k**	
Cost of the initiative: one-time						
Build the four gates	S$504k	–	–	–	–	4 people × 6 months × 21 days × S$1,000 a day: forecast, ordering, counter comparison, review
Data integration and set-up	S$250k	–	–	–	–	POS sales, app sign-ups and supplier order feeds; lump sum
Total one-time cost	**S$754k**	**–**	**–**	**–**	**–**	
Cost of the initiative: recurring						
Maintenance team	S$504k	S$504k	S$504k	S$504k	S$504k	2 people × 12 months × 21 days × S$1,000; counted from year 1 (conservative)
Platform and licences	S$60k	S$180k	S$300k	S$420k	S$540k	Store-years × S$50 a month × 12
Gate 4 reviews	S$200k	S$200k	S$200k	S$200k	S$200k	Openings × 1 analyst day × S$1,000: updated scenario against the original plan
Total recurring cost	**S$764k**	**S$884k**	**S$1,004k**	**S$1,124k**	**S$1,244k**	
Total cost	**S$1,518k**	**S$884k**	**S$1,004k**	**S$1,124k**	**S$1,244k**	
Net benefit	**(S$1,216k)**	**(S$127k)**	**S$209k**	**S$544k**	**S$879k**	**Total benefit minus total cost**
Cumulative net	**(S$1,216k)**	**(S$1,343k)**	**(S$1,135k)**	**(S$591k)**	**S$289k**	**From year 1**

Sensitivity, cumulative net after 5 years. one-time costs double: S$465k short, no payback; counter saving halves: S$2,558k short, no payback; openings fall to 100 a year: S$1,493k short, no payback.

Read with care. No sales revenue: we have no price or demand-elasticity assumption, so the benefit is the modelled avoided cost from slide 9, against a mixed counter at every opening; it is not a demonstrated AI saving. The cost lines are our approved illustrative assumptions (A1, business case), not Chagee or vendor figures. Values in S$ thousands; brackets are negative.

Appendix A4 · revenue and cost analysis

Handout only. Benefit lines come from the benefit slide's calculation (sim/ volumeCurve and provision); cost lines are the approved business-case assumptions (illustrative). No sales revenue is modelled.

Sources: Openings: L-jiemian (2026 only; held flat after). Benefit: benefit_values in deck/build_deck.py from data.json. Costs: assumptions.json business_case (approved, illustrative).

In the peak hour, robots hand over a cup in about 49 seconds; a counter like today's takes about 2.6 minutes

INTERACTIVE EXPLAINER STORE REPLICA: TWO COUNTERS IN THE PEAK HOUR, SIDE BY SIDE

Illustrative layout after a Chagee tea bar: order right, brewing behind the counter, pick-up left. Choose each counter; people move as the Week 5 bucket brigade; staff and arrivals from the cost model.

Number = worker speed · cup above = drink in hand · faded = walking back · red ring = held back by the colleague ahead · ▲ = handover. Robots stay put; cups move. Both counters see the same customers.

Printed at minute 20 of the peak hour, moderate surge: people slowest first (top) against fastest first (bottom).

Time to serve, cost model (median · slowest tenth · lost):

Today's counter **2:34** · 5:03 · 2% lost All-human **2:42** · 5:10 · 2% lost All-robot **0:49** · 1:19 · 0% lost

Observed: not measured yet

OUR VIEW

Robots buy speed in the peak; whether it pays is the counter-cost slide.

Appendix A5 · store replica and time to serve

Handout only (appendix): detail behind the counter-flow slide. Two counters laid out like a Chagee tea bar, seeing the same customers: order on the right, brewing behind the counter, pick-up on the left. It plays on its own. Top: people as the Week 5 bucket brigade, slowest first. Each worker carries a cup towards pick-up; the last hands it over, walks back and takes over from the colleague behind, so the line balances itself. Bottom: the same people, fastest first. The fast worker keeps catching the slow one and is held back, the red ring, and fewer cups get out. Switch the bottom to All-robot: nobody moves, the cups move from machine to machine. The times come from the cost model, in the line underneath: today's counter hands over a cup in about 2.6 minutes at the median, an all-robot counter in about 49 seconds; open it for the chart. None of these is measured. The counter-cost slide puts a price on each counter.

Sources: Semi-automation (machine dispenses the formulation): L-unsw; Chagee Express semi-automated machine: L-cyberrt. Layout: illustrative, after a Chagee tea-bar storefront (order right, pick-up left). Animation: sim/store.js (Week 5 brigade rules, illustration.walk_back_speed). Times and lost orders: sim.js serveTimes, a read-out of the cost model's peak hour. No measured serve time exists in our sources; the informal sub-one-minute target (l-leeyen) is not used.
