CHAGEE SINGAPORE

FORECAST THE PEAK, SHARE THE COUNTER

THREE DECISIONS, THREE OWNERS: MEMBERSHIP, THE COUNTER AND THE NEXT OUTLET

OPIM639 · GROUP 3 · KEZIAH, JIN, AYUMI, REVAN · OCTOBER 2026

SPEAKER NOTES · TITLE

Good morning. We are Group 3. Our company is Chagee in Singapore, and our story has three connected decisions: grow demand through a better membership experience, serve that demand well at the counter, and open where customers are underserved.

Each part has its own owner and its own tools, and slide 04b shows how network effects run through them: membership and product teams with a network-effects model, outlet operations with forecasts, machines and the bucket brigade, and expansion planning with app-search clusters. After the main story, a short section of things to consider holds the extensions.

Timing: title and agenda together, about twenty seconds.

Agenda

01 **Chagee in Singapore**
How it earns and sells

02 **From farm to cup**
Where the supply chain is stable, and where it is not

03 **The data trail**
What every cup already records

04 **Our scope**
Grow demand, serve it well, then expand where customers need us · 04b how we use network effects

05 **Grow · is tiering up worth the effort?**
The problem and the network-effects model

06 **Grow · squads and personalised suggestions**
The app prototype · 06b member signals to forecasts

07 **Grow · the CRM manager's decision**
Reward level, AI cost and a three-arm pilot

08 **Serve · demand moves by the hour**
The problem, forecast capacity · 08b how the crew shares the work

09 **Serve · which steps justify a machine?**
People or machines · 09b the operations manager's decision

10 **Expand · where next?**
The problem, DBSCAN and the demand model · 10b the expansion manager's decision

11 **Our recommendation**
Three decisions, three owners, three pilots

\+ **Things to consider** Back
A new market: Australia · site scores · the decisions in detail · the size of the benefit

SPEAKER NOTES · AGENDA

The first four slides set the context and the scope. Then three chapters, each with the same shape: the business problem, the solution, and the manager's decision. Grow, for the CRM manager; serve, for the outlet GM or operations manager; expand, for the expansion manager. Then our recommendation. Click any line to jump there.

Singapore outlets are company-owned, and every channel ends at 1 counter

Company-owned stores, one data system: order and app data sit together

HOW A SINGAPORE CUP IS SOLD

SINGAPORE: COMPANY-OWNED STORES

SG **Chagee runs its Singapore outlets itself**, not through franchisees, so the counter design, roster and equipment are Chagee's own decisions (confirmed by the project owner).

Global context only: group-wide, most FY 2025 net revenue came from franchising (88%, secondary source). That does not describe Singapore.

SG Singapore outlets run under one company and one data system (Chagee source, anonymous)

In store	Walk-in (app order; tourists can order at the counter, to confirm)
Chagee app	order ahead, collect
Delivery	third-party delivery apps (e.g. Grab); no Chagee-run delivery

→ **One counter** every channel's cup is made here

44 outlets, ground-floor mall units by preference; kiosks in basements and MRT stations at entry in 2019

- **Company-owned, shared data**

  Singapore outlets are **company-owned** (confirmed by the project owner). They run under **one company and one data system** (Chagee source, anonymous).

  Opportunity: A counter design or roster rule rolled out across outlets.

- **Chagee-App**

  An **order-ahead, self-pickup app**; in Singapore, **in-app ordering and delivery** followed the reopening queues. Chagee **collects personal and transactional data**.

  To confirm: the app's share of Singapore orders; whether searches or location are logged.

  · CHAGEE App Store listing · Vulcan Post, Oct 2024 · Chagee Form 20-F, FY 2025

- **Why Chagee?**

  A **fast-growing, playful** brand with **heavy app use**.

  Likely to have **rich order data** and **room for AI** to help the stores.

TAKEAWAY | Whatever the channel, every order ends at one counter. Peak hour is where an outlet wins or loses.

SPEAKER NOTES · CHAGEE IN SINGAPORE

Step through four points. One: Chagee Singapore operates a company-owned model, not a franchise model: Chagee runs these outlets itself, so the counter, the roster and the machines are its own decisions. Our project owner confirmed this. If asked about the group: across Chagee worldwide, most FY 2025 net revenue came from franchising, about 88%, from a secondary source. That is global context only; it does not describe Singapore.

Two: Singapore outlets run under one company and one data system, according to an anonymous Chagee source. That a counter design or roster rule could be rolled out across outlets is our reading, not something we were told.

On the app card: Chagee has an order-ahead, self-pickup app, per its App Store listing, and Vulcan Post reports that Chagee Singapore rolled out in-app ordering and delivery after the long reopening queues. Its Form 20-F for FY 2025 says the business generates and processes personal and transactional data. What we cannot back publicly: the app's share of Singapore orders, and whether searches or location are logged; the App Store privacy label lists precise location as not linked to the user. Those are to confirm with Chagee.

Three: 44 outlets, by the store directory in October (press reports vary: 44–46). Chagee prefers ground-floor mall units.

Four: walk-in, app orders for collection, and third-party delivery orders all end at the same counter. Ordering is app-first: walk-ins order in the app, and the source mentioned counter ordering only as an exception for tourists, which we will confirm. The Chagee app is for ordering ahead and collecting; all delivery goes through third-party apps such as Grab, by the same Chagee source, and there is no Chagee-run delivery. That is why we look at the counter. About fifty seconds.

Supply is standard and pre-planned. Counter feels demand within minutes

Tea leaves travel one standard route. Only fresh milk and fruit are bought locally.

FOLLOW ONE CUP · STEP THROUGH

Source

Tea leaves from **Yunnan** through standard channels for every market

DATA CREATED

Shipments, lead times

Local: fresh milk, fruit

Warehouse

Separate central and regional warehouses keep storage and logistics costs down

DATA CREATED

Stock vs par, expiry

Outlet Counter

Machines: brew each cup from a scanned recipe
People: Ice, toppings and hand-over

DATA CREATED

Cups by hour

Wait times (to confirm)

Last Mile

Self-collect via app, or delivery via **third-party** apps such as Grab.
Riders wait at the same counter

DATA CREATED

Orders by channel

Rider wait (to confirm)

Customer

Orders through app and **collects** at the counter.

DATA CREATED

App orders, drop-offs

- **Stable upstream**
  Standard sourcing, regional warehouses and forecast-led restocking: Chagee already plans this part.
  YF Chuhai; Chagee Form 20-F
- **Volatile downstream**
  Demand at a counter **moves by the hour**: lunch, a mall event, rain, a new drink launch.
- **So we stop at the counter**
  Question is: How many people the counter needs this hour? And how do they work? (Not shipment)

TAKEAWAY | Chagee already plans its stock (public sources). People are deployed on local expertise, by the GM and outlet teams (Chagee source, anonymous); that is the call we model.

SPEAKER NOTES · FROM FARM TO CUP

Press play and the cup travels farm to customer. Sourcing is standard; only fresh milk and fruit are local (YF Chuhai). Chagee runs central and regional warehouses (Form 20-F) and already plans restocking from forecasts.

The volatile part is the counter, the red chips. At the counter, a Chagee source who asked not to be named told us the GM and outlet teams deploy people on local expertise; we model how a forecast could support those calls. Under time pressure, one sentence: supply is planned ahead; the counter runs on local judgement. About forty seconds.

Orders are already recorded; the other inputs a forecast needs are candidates to confirm

Four data sources and six decisions they could feed. We follow the four that start in the app and end at the counter.

WHICH SOURCE FEEDS WHICH DECISION · STEP THROUGH

	Store and production	App and members	Delivery	Supply and context
Demand forecasts	Cups per hour by drink and channel	Member repeat demand	Orders per hour by platform	Weather, holidays, launches
Staffing and prep	Wait times, machine logs	Pickup no-shows	Hand-over peaks	Labour hours vs cups per hour
Replenishment	Drink mix per outlet	Launch trial rates	Group-order toppings	Ingredient use, expiry, par
Queue and capacity	Wait time, footfall vs sales	Store-select drop-offs	Rider wait at counter	Stock-outs at peak
Site selection	Sales density per outlet	"No store nearby", home and work	Distance and fee by postcode	Mall footfall, competitors
Menu and promos	Drink share, customisation	Trial and repeat, voucher uplift	Delivery basket mix	Collab calendar

White chips: core input; grey: refines it; red rows: our scope. Wait times, footfall, searches and location are to confirm.

- **Known and to confirm**

  Known: orders by channel and time (point of sale, app, Grab).

  To confirm: searches, customer location, wait times and walk-aways; some may need new logging.

- **The app is the link**

  Only the app ties a cup to a person. That needs consent and care under Singapore's data protection law (PDPA).

- **What we take forward**

  Demand forecast, then staffing, then queue capacity: one chain that ends with the outlet's roster and counter.

TAKEAWAY | Orders by hour are recorded; searches, location, waits and walk-aways need confirming. Today, GM and outlet teams deploy people on local expertise (Chagee source, anonymous); we show how a forecast could support those calls.

SPEAKER NOTES · THE DATA TRAIL

Each step lights up one decision and the data that feeds it. Skip to the last step under time pressure: our scope is the three counter rows: forecast, staffing, queue.

This list is our reading of what Chagee's systems could record. Orders by channel and time are known; searches, customer location, wait times and walk-aways are candidates to confirm, based on public material and our industry conversation, not a Chagee data dictionary. About fifty seconds.

Grow demand, serve it well, then expand where customers need us

Three connected decisions, three owners. Each chapter: business problem → solution → manager's decision.

THREE CONNECTED DECISIONS · STEP THROUGH

1 Grow demand through a better membership experience

OWNER · CRM MANAGER

- **Problem:** customers may not find tiering up worth the effort (informal source, anonymised, to validate).
- **Solution:** squad-based progression, personalised drink suggestions and recipient-chosen gifts; member choices become signals.

Squads and the network-effects model: **analytics, not AI** · **AI**: personalised suggestions and demand forecasting from squad signals

DECISION
Pilot squads with personalised recommendations? At what reward level?

Judged on tier progression, satisfaction, incremental orders and contribution after reward and AI costs.

05 to 07: problem and effort model, app prototype, 06b signals, decision

→

"A more engaging membership experience must be matched by reliable fulfilment."

2 Serve that demand reliably in store

OWNER · OUTLET GM, OPERATIONS MANAGER

- **Problem:** demand moves by the hour; rosters and fixed posts may not.
- **Solution:** a forecast sets the capacity needed; the counter simulation compares ways to provide it.

Predictive AI forecasts demand · the **bucket brigade** is an operations rule · **machine automation** does fixed steps

DECISION
How many to roster, how they share the work, and which steps justify automation?

Judged on waiting time, walk-aways, productivity and operating contribution, with forecast error tested.

08 to 09b: problem and forecast, sharing, automation, decision

→

"Serving customers better also means being available where demand remains underserved."

3 Expand where customers need us

OWNER · EXPANSION MANAGER

- **Problem:** a new outlet can mostly move sales from nearby stores, while some customers lack access.
- **Solution:** DBSCAN finds clusters of unserved app searches; a separate demand model estimates sales and cannibalisation.

Unsupervised ML plus an assumed demand model and a five-year P&L

DECISION
Which location to investigate or pilot next, and do its incremental returns justify the investment?

Judged on access, net additional demand, incremental profit, investment, payback and downside. New markets: area features and scenarios instead.

Unpacked in slides 10 and 10b; new markets under Things to consider

TAKEAWAY | Make membership worth joining → make orders worth returning for → open where demand remains underserved.

SPEAKER NOTES · OUR SCOPE

Our scope is three connected decisions, each with its own owner, and each chapter runs the same way: the business problem, a demonstration of the solution, then the manager's decision.

First, grow demand, owned by the CRM manager. The problem, from an informal source we still have to validate: customers may not find tiering up worth the effort. The solution is squad-based progression with personalised drink suggestions and recipient-chosen gifts. The squad model is analytics, not AI; the suggestions and the forecasts from squad signals are the AI part. The decision: pilot it or not, and at what reward level, judged on tier progression, satisfaction, incremental orders and contribution after reward and AI costs.

Second, a more engaging membership experience must be matched by reliable fulfilment, owned by the outlet GM or operations manager. Demand moves by the hour; rosters and fixed posts may not. A forecast sets the capacity needed, and the counter simulation compares ways to provide it: the bucket brigade as an operations rule, and machines for fixed steps. The decision: how many to roster, how they share the work, and which steps justify automation.

Third, serving customers better also means being available where demand remains underserved, owned by the expansion manager. DBSCAN finds clusters of unserved app searches; a separate demand model estimates sales and cannibalisation, and a five-year P&L the returns. In a new market without app history, external area features and demand scenarios stand in.

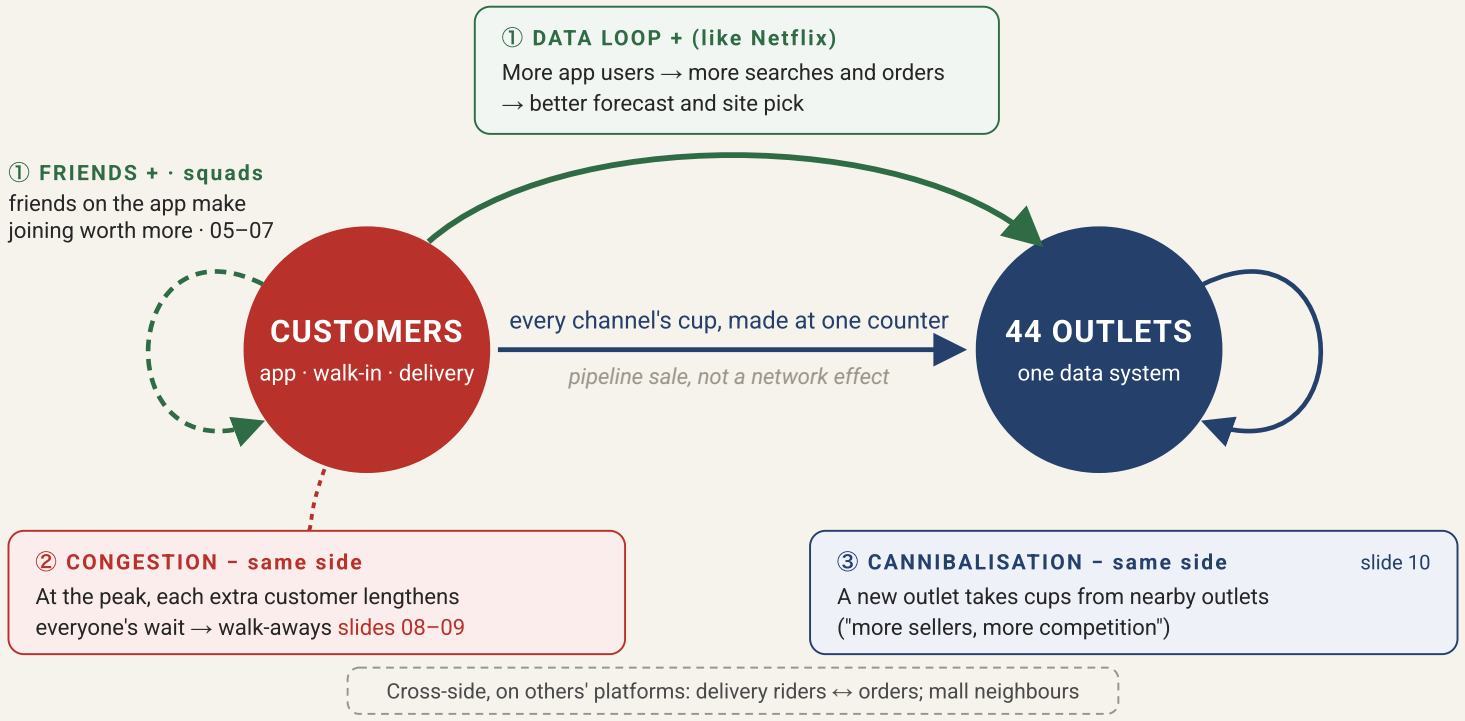

Be clear that this is a connected business narrative, not one validated causal model. We do not carry any simulated membership uplift into the store-demand or expansion numbers; each section stands on its own assumptions. About one minute.

Course link · cross-side vs same-side network effects (eBay)

Chagee's network effects sit on the customer side: we grow the friend and data loops, then cap the crowding they bring

Our reading: Chagee sells its own tea, so there is no seller side to match. Part one grows the positive loops; parts two and three cap the crowding.

WHERE CHAGEE SITS ON THE DIAGRAM · CLICK A LOOP

① GROW · PART ONE · 05 TO 07

Make friends worth more, feed the data loop

Squads: friends taking part raise the features' value (not AI). **Why Chagee:** app-first and member-led: **257 million** members group-wide; repeat members place **more than 78%** of orders (earnings call, Aug 2026; SG to confirm).

② CAP · PART TWO · 08 AND 09

Absorb the peak crowd

Forecast crew plus a bucket brigade: event day walk-aways **54%** → **1.2%** of peak-hour orders.

③ CAP · PART THREE · SLIDE 10

Count cups added, not sold

Of 837 cups at the new site, **106** (13%) move from nearby outlets. The score subtracts them.

NOT OUR LEVER

Delivery apps and malls own the cross-side effects; their riders still count in our peak.

Takeaway | Grow the friend and data loops, then make sure the counter and the outlet map can absorb the extra customers.

SPEAKER NOTES · NETWORK EFFECTS

This is how the three parts use network effects. A lens from the course: on eBay, buyers and sellers attract each other, a cross-side effect. Chagee is not that, in our reading: it sells its own tea, so customers to outlets is a pipeline sale. Its network effects sit on the customer side.

Two we grow, in part one. Friends: with squads, each friend on the app makes joining worth more to the others; slides 05 to 07 model that with an effort score and test whether it pays. That part is analytics and product design, not AI. And the data loop: more app use gives more search and order data, so the forecast and the site pick get sharper. That is why we chose Chagee: on its second-quarter 2026 call it reported 257 million registered members, and members with two or more purchases placed more than 78% of orders. Group-wide figures; Singapore's app share is to confirm.

Two we cap. Part two, congestion: at the peak every extra customer lengthens everyone's wait; a normal-day roster on an event day loses about 54% of peak-hour orders, and a forecast crew with a bucket brigade brings it to about 1.2%. Part three, cannibalisation: a new outlet takes cups from its neighbours; of 837 cups at the app-search site, 106 move from nearby outlets.

Cross-side effects exist, but on others' platforms, delivery apps and malls: not our lever. And we do not carry any modelled membership uplift into the counter or outlet numbers; each part stands on its own assumptions. About fifty seconds.

Course link · Topic 8, network effects

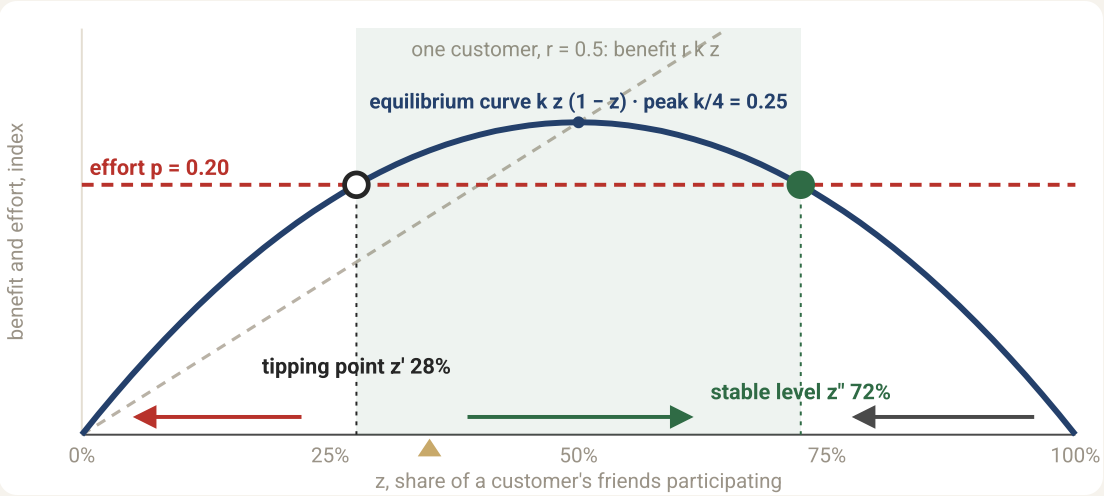

Squads could make progress worth the effort, but only once enough friends take part; below the tipping point, participation shrinks

BUSINESS PROBLEM Customers may not think the effort of progressing through membership tiers is worthwhile. Informal source, anonymised · to validate A concern raised with us, not a measured finding that customers never move tiers. Below: a network-effects model (analytics, not AI) in illustrative index units.

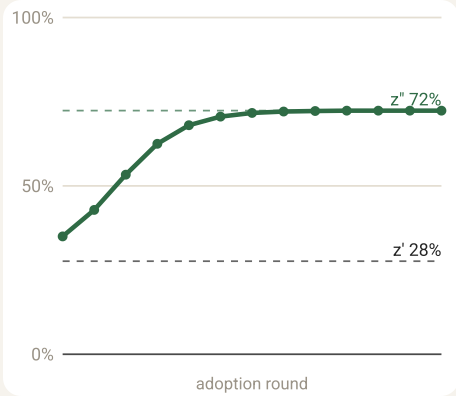

BENEFIT AGAINST EFFORT · ILLUSTRATIVE INDEX

Join when **perceived benefit ≥ effort** | One customer: **r × k × z ≥ p**

Equilibrium, interest r = 1 − x across customers: **p = k z (1 − z)**

PARTICIPATION, ROUND BY ROUND

SHOWN

Effort score 0.20 (an illustrative index, not money), value of friends k 1.00, starting participation 35%.

THE SYMBOLS

- **r** individual interest, from none to full
- **k** value of friends participating
- **z** share of a customer's friends participating
- **p** effort of joining or progressing

TAKEAWAY | Tipping point **28%**, stable level **72%**. Starting at 35%, participation rises to about **72%**. Illustrative.

SPEAKER NOTES · MEMBERS: WHEN DOES JOINING FEEL WORTH IT?

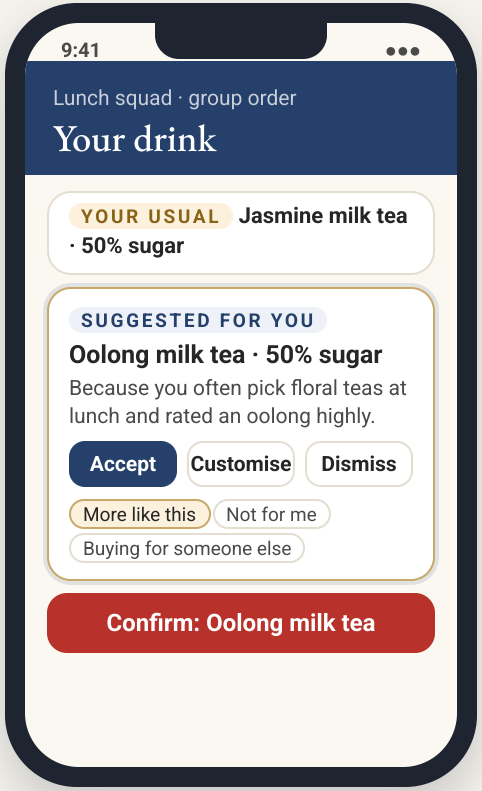

Part one starts with a business problem. A Chagee staff member told us, informally and in paraphrase, that the barrier to levelling up is whether customers think the effort of tiering up is worth it. Treat that as an insight to validate, not a measured finding: we have no data showing customers never move tiers. Our proposed answer is squad-based progression, where friends taking part make membership worth more. To see when that works, we use the network-effects model from Topic 8. It is an analytics model, not AI. One customer joins when the benefit beats the effort: interest times the value of friends times the share of friends on, against the effort score. Customers differ in interest, so the share who would join traces a hump.

Where the effort line crosses the hump there are two points. Below the lower one, the tipping point, participation falls back to zero; above it, it climbs to the stable level. At our default the tipping point is about 28%. Raise the effort and the two points close in, then vanish: the app stalls from any start. About thirty seconds. Tables and the derivation are in the appendix.

Squads make friends' orders count for everyone, and personalised suggestions make choosing easier: two hypotheses to test

PROPOSED EXPERIENCE — ILLUSTRATIVE

1. See your progress and start a squad
2. Invite friends from the share sheet
3. Choose your drink: your usual, or a suggestion
4. Each friend confirms their own drink
5. Collect the order: everyone's progress moves
6. Send a friend a drink
7. The friend picks from suggestions made for them

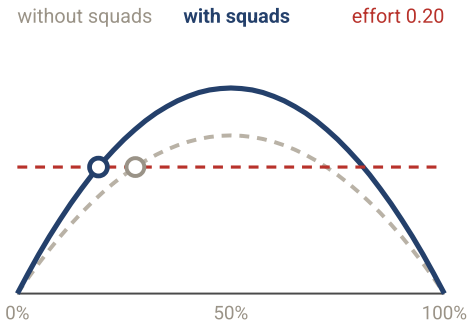

BASELINE AND AI
Recalling your last order is the baseline. The proposed AI part ranks other drinks from your own choices, acceptances and dismissals. Your feedback teaches it; "Buying for someone else" keeps that drink out of your profile.

WHY IT MATTERS
Easier choices may lower the effort, p, further. A hypothesis to test, like k.

Proposed experience with illustrative data and rules, not Chagee's; nothing is learned from real customers.

FROM THE APP TO THE MODEL · ASSUMPTIONS TO TEST
Shared benefits are hypothesised to raise **k**, the value of friends participating. Personalised suggestions, simpler progression or a launch incentive may lower **p**, the effort. Each member's picks and feedback also become signals (06b). Not measured effects.

WITHOUT SQUADS / WITH SQUADS

TAKEAWAY | At slide 05's effort of **0.20**, squads (assumed k 1.00 → 1.30) would move the tipping point from **28%** to **19%**: fewer friends need to be on before joining feels worth it. Assumptions to test, not measured effects.

SPEAKER NOTES · THE PROPOSED SQUAD EXPERIENCE

This is the solution, as an illustrative prototype; the rules are ours, not Chagee's. Two parts, kept apart: squads, a product design, and personalisation, the AI part, which suggests a drink from each member's own choices and lets a gift's recipient choose privately. Click through: a member sees their progress and starts a squad, invites friends, then chooses a drink, with a suggestion they can accept, customise or dismiss and feedback such as not for me. In the shared basket each friend confirms their own drink, and preferences are saved to whoever chose, not whoever paid. When the order is collected everyone's progress moves. Last, gifting: the recipient picks privately from options ranked for them. Those picks and that feedback are the signals on the next slide.

Why it matters for the model: our hypothesis is that shared progress raises the value of friends, k, so the hump rises and the tipping point falls, from about 28% to 19% at the default effort. The stalled case is the headline: at a high effort the app never takes off without squads, and with them it can. These are assumptions to test, not measured effects. About thirty seconds.

Every group order helps us understand—and serve—customers better

SYNTHETIC · PICKUP WINDOW 13:00 TO 13:30

1 Collect

Completed purchases	documented
Selected outlet and in-app order	documented
Drinks and customisations	to confirm
Pickup time chosen	to confirm
Group size, confirmed quantities	proposed
Suggestion accepted, edited, dismissed	proposed
Gift sent and redeemed	proposed

2 Predict

Expected cups in the window = **confirmed + predicted, not yet confirmed**

At -10 min: 5 baskets open, 4 invitees not yet confirmed × 15% learned chance; 0 gifts unredeemed × 6%; 0.2 cups expected from baskets not yet opened. Usual = calendar baseline less its squad share.

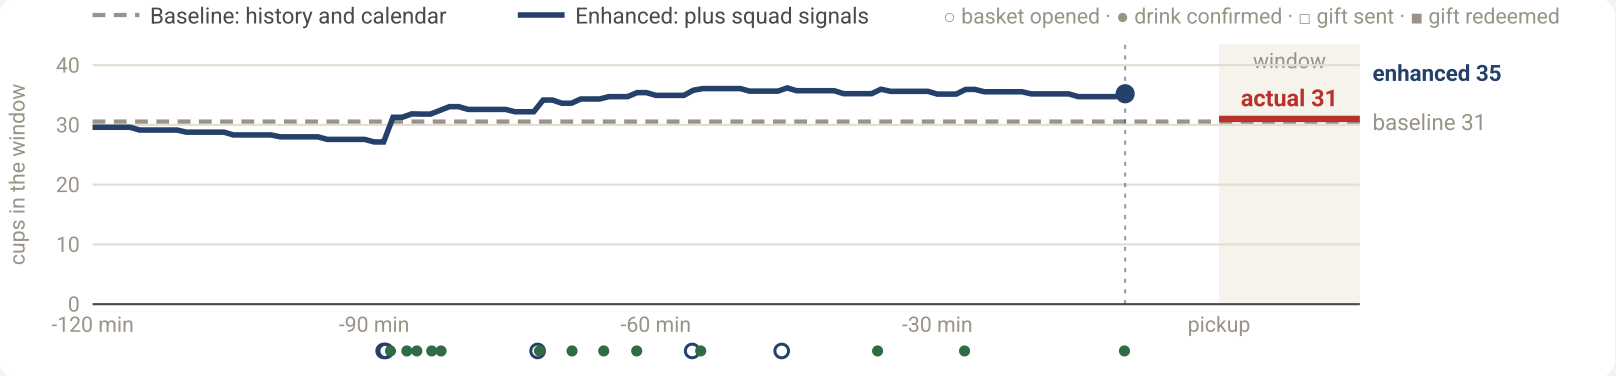

3 Act

Prepare
Jasmine 16 · Oolong 8 · Black 7
drinks to have ready

Staff
1 person, 13:00 to 13:30
the window's crew

Counter
one person, machines on tea and milk · load 70%
how the line is run

Pickup estimate
ready in about 3 min
shown to customers (rough)

SHOWN

Typical day (synthetic), squad share 30%, forecast at -10 min, actual revealed. Window 13:00 to 13:30.

WIN-WIN

Customers: easier choices, less group-order coordination, more reliable pickup times.

Chagee: better preference signals and a clearer view of what to prepare, where and when.

PRIVACY

Preferences are collected openly, with consent (PDPA). Each member's history stays out of the shared squad view.

TAKEAWAY | Typical day: actual **31** cups. At -10 min the baseline was off by **0.4**, the enhanced forecast by **4.2**: worse today, because walk-in demand moved and squads cannot see it. One synthetic day; averages are in the appendix.

NEXT Is it worth piloting, and at what reward level? The CRM manager's decision; the outlet's response to this demand is part two.

SPEAKER NOTES · EVERY GROUP ORDER HELPS US SERVE CUSTOMERS BETTER

The squad experience is also a data source. As the course put it for online retailers, an app can capture demand data, not just sales data. Step one, collect: the drinks people choose and customise, group size and confirmed quantities, the outlet and pickup time, whether they took a suggestion, and completed purchases and gift redemptions. Orders and pickup outlets are what an order-ahead app already records; the squad fields are proposed and need consent.

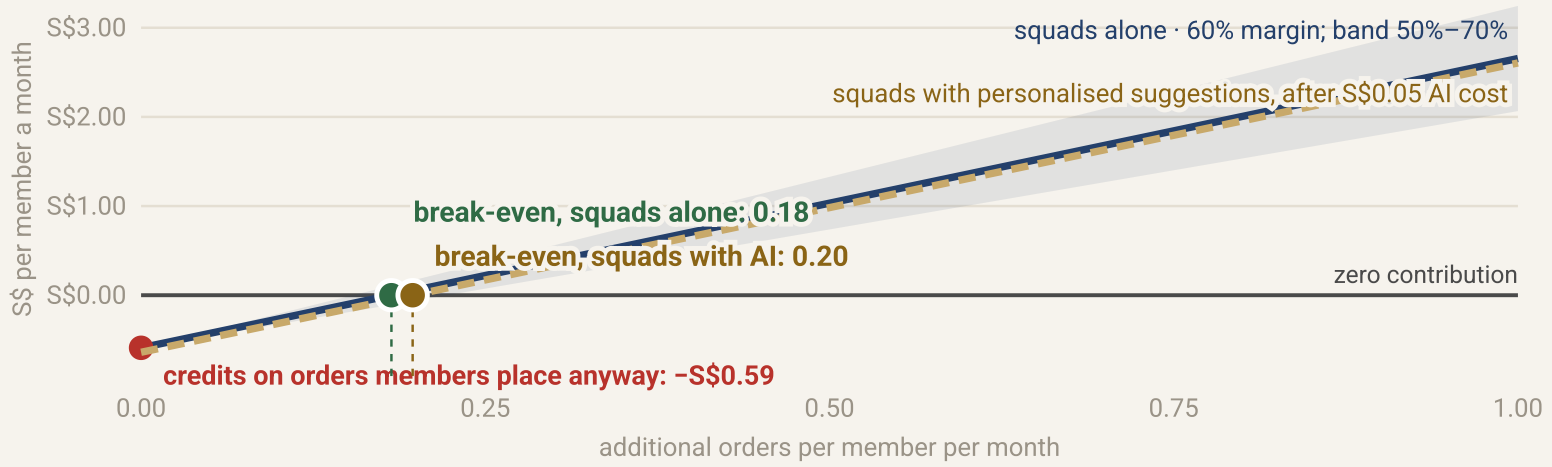

Step two, predict, for one outlet's pickup window: expected cups are the cups already confirmed, plus a prediction of those not yet confirmed. An open basket or an unredeemed gift is not a drink; it counts only at the chance learned from past windows, and a confirmed cup is never counted twice. Step three, act: the forecast sets what to prepare, the crew for the window, how the counter is organised and the pickup time customers see.

Then play it. This is synthetic: the squad signals help only because we assumed they carry information, so watch the mechanics, not the score. On some days the enhanced forecast is worse, because walk-in surges are invisible to squads. Averaged over 400 synthetic windows it is off by about 5.3 cups ten minutes before, against 7.3 for the calendar baseline; with no squad share the two are identical. The appendix has the table.

Both sides gain: easier choices and reliable pickup for customers, a clearer view of what to prepare for Chagee. Personalisation may lower the effort from slide 05, but that is a hypothesis, and we do not turn adoption into extra orders. How the outlet organises people and machines to serve this demand is part two. First, the CRM manager's decision: is it worth piloting, and at what reward level? About one minute.

Pilot squads with personalised suggestions only at a reward level that members' extra orders can pay for, after AI costs

PER MEMBER A MONTH · S$ · ILLUSTRATIVE

SHOWN
Credit 5.0% of the S$5.90 price; 2.0 group orders a month anyway; AI cost S$0.05 a member a month; margin 60% (band 50%–70%).

THE PILOT · THREE ARMS, SINGAPORE
A today's membership · **B** squads · **C** squads with suggestions. B against A: the squad effect; C against B: the personalisation effect. Orders are measured, not read off the model.

CAVEATS
Consent for friend and preference data (PDPA); tier rules, AI cost and credit to confirm.

MANAGER'S DECISION
CRM manager

Should we pilot squad-based progression with personalised recommendations, and what reward level makes it worthwhile for customers and Chagee?

PROPOSED
Pilot the three arms at a **5.0%** credit. Squads must add about **0.18** orders per member a month to cover the reward; personalisation about **0.02** more to cover its S$0.05 cost (**0.20** in all).

PROCEED IF, ARM AGAINST ARM
- tier progression rises (B against A)
- customer satisfaction holds or rises
- incremental orders reach the break-even (B against A, and C against B)
- contribution after reward and AI costs is positive

NEXT A more engaging membership experience must be matched by reliable fulfilment.

SPEAKER NOTES · PILOT SQUADS WITH PERSONALISED SUGGESTIONS?

The decision for part one belongs to the CRM manager: should we pilot squad-based progression with personalised recommendations, and what reward level makes it worthwhile for customers and Chagee? The line is the contribution per member a month after the reward, the group-order credit. It starts below zero, because the credit is also paid on orders members would have placed anyway, and rises with each extra order. At a credit of 5% squads alone break even at about 0.18 extra orders a month at our base margin. Push the credit up to the margin and it never breaks even.

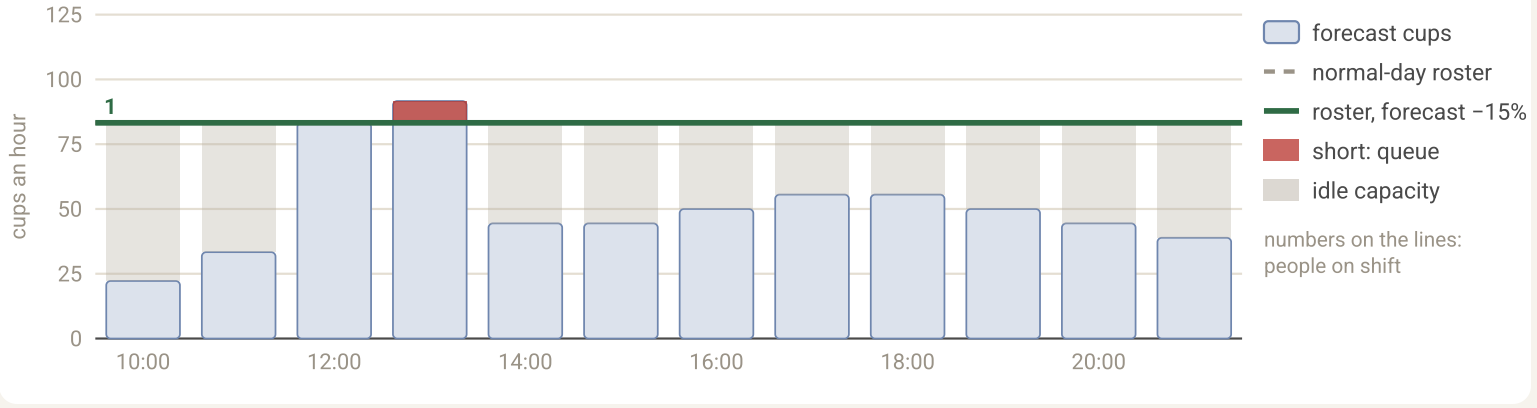

Step four adds personalised suggestions. They cost something to run; we assume S$0.05 a member a month, a placeholder to replace with a real quote. That shifts the line down: break-even moves to about 0.20 extra orders, so personalisation must add about 0.02 orders a month of its own on top of squads.

That is why the pilot has three arms: today's membership, squads, and squads with personalised suggestions. Squads against today shows the squad effect; adding suggestions shows the personalisation effect. Proceed only if tier progression rises, satisfaction holds, the extra orders reach these break-evens, and contribution after reward and AI costs is positive. We measure orders directly and do not read purchases off the adoption model. Then the transition: a more engaging membership experience must be matched by reliable fulfilment. About forty-five seconds.

A roster that does not move with demand leaves the peak short and the quiet hours idle; a forecast sets the capacity each hour needs

BUSINESS PROBLEM Demand changes by the hour; staffing and fixed station assignments may not, leaving queues, walk-aways or idle capacity. Observed people deployed on local expertise (Chagee source, anonymous); long reopening queues (Vulcan Post). Simulated everything below. To confirm Chagee's waits and walk-aways.

CUPS AN HOUR AGAINST CREW CAPACITY · BUSY DAY

HOW MANY PEOPLE · THIS SLIDE
Forecast-informed staffing
Predictive AI estimates the capacity each hour needs.

HOW THEY SHARE THE WORK · 08B
Bucket brigade or fixed posts
An operations rule, compared in the counter simulation.

WHICH STEPS MACHINES TAKE · 09
People or machines
Automation of fixed steps, compared in the same simulation.

SHOWN
Busy day, today's split, forecast −15% low. Other days: the deck's interactive version.

SENSITIVITY TO FORECAST ERROR · PEAK HOUR · BUSY DAY

FORECAST	CREW	AWAY	WAIT	S$/DAY	CUPS/PP
−30% low	1	20.8%	6:22	372	70
−15% low	**1**	**20.8%**	**6:22**	**372**	**70**
exact	2	0.0%	1:14	402	45
+15% high	2	0.0%	1:14	402	45
+30% high	2	0.0%	1:14	402	45

Bucket brigade, mean of 20 runs. Cost: the day's roster and machines. Error steps are scenarios, not Chagee's measured accuracy.

TAKEAWAY | Forecast −15% low: **1** at the peak, **20.8%** walk away, S$372 a day; peak-hour contribution **S$233** against S$287 with an exact forecast.

SPEAKER NOTES · DEMAND MOVES BY THE HOUR

Part two. A more engaging membership experience must be matched by reliable fulfilment. The business problem: demand changes by the hour, while the roster and fixed station assignments may not. What we have observed: a Chagee source who asked not to be named told us outlet teams deploy people on local expertise, and Vulcan Post reported long queues at the Singapore reopening. What we have not observed: Chagee's own wait times and walk-aways. Everything on the chart is simulated, on our assumptions.

Step one is the forecast: cups an hour from historical order shares and the calendar. App signals, like the squad signals on 06b, could refine it nearer the time, but they are not in these numbers. Step two: keep the normal-day roster on a busier day and the peak runs short, in red, while the morning crew stands idle, in grey. Step three: the forecast roster follows demand. Keep three things apart: the forecast says how many people; the bucket brigade is a rule for how they share the work; machines decide which steps people do at all. The next two slides compare those.

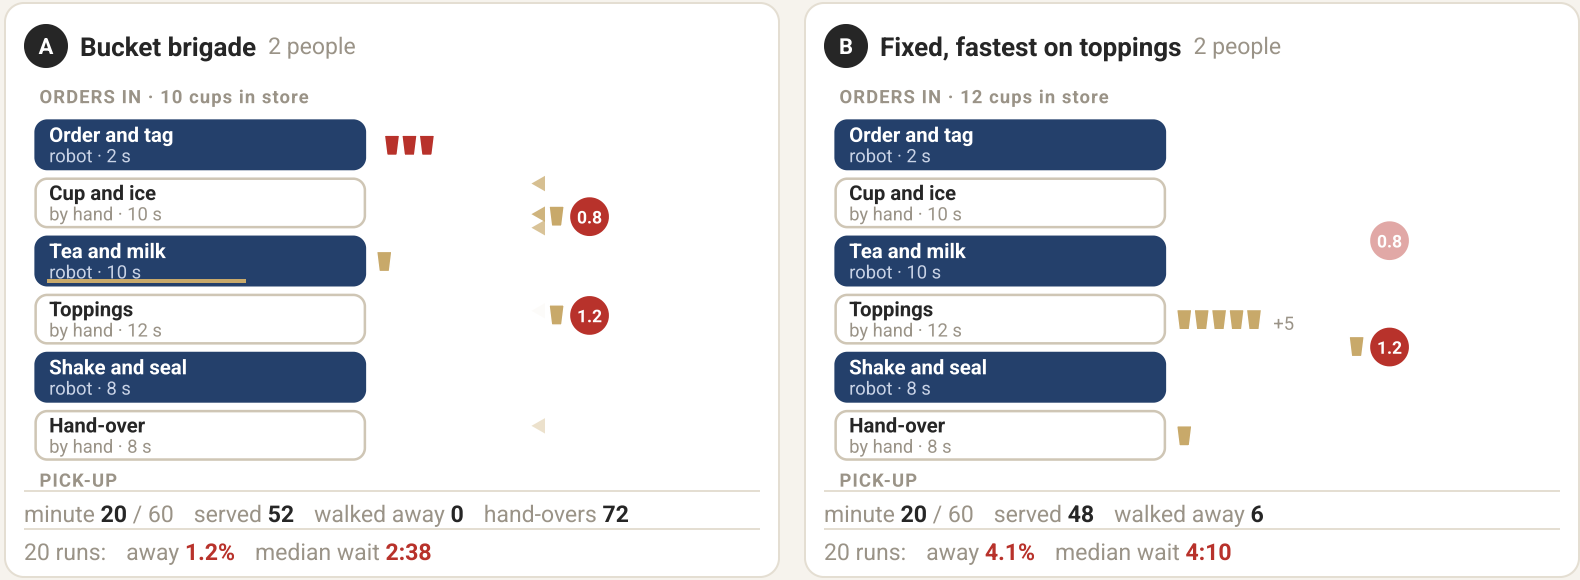

Step four, the sensitivity. On a busy day, a forecast 15% too low puts on 1 person at the peak instead of 2, and walk-aways go from 0.0% to about 21%. A forecast too high costs little: about S$15 more a day on an event day. Being short costs more than being long. These error steps are scenarios, not Chagee's measured accuracy. About one minute.

Course link · Week 5 and Week 6 · the bucket-brigade simulation

With a lean roster, a bucket brigade keeps cups moving without knowing who is fastest

The forecast set how many people (08); here, how they share the hand steps. Today's split (our scenario), two sharing rules side by side.

PEAK HOUR · SAME CUSTOMERS ON BOTH SIDES

Red circle = a person (number = speed) · gold ring = held back · faded = walking · ▲ = hand-over · navy = robot · red cup = waiting for a person

ALL THREE RULES, MEAN OF 20 RUNS

EVENT DAY, 2 PEOPLE	WALKED AWAY	MEDIAN WAIT
Bucket brigade	**1.2%**	**2:38**
Fixed, fastest on toppings	4.1%	4:10
Fixed, slowest on toppings	34.9%	9:47

At the people on side A. A customer leaves if the wait would pass 5 min. With spare people, a well-assigned fixed line is as good or a little faster.

- **Why lean is where it counts**
  Work flows to whoever is free, so the line balances itself (Topic 5). Fixed stations are only as good as the guess of who is fast.

Machines = automation, each side's equipment, held fixed. **AI = AI-assisted staffing**: the forecast sets the crew; customers and sharing rule unchanged. Event day · peak hour · mean of 20 runs · illustrative assumptions

WITHOUT AI INTELLIGENCE normal-day roster	**A** Bucket brigade: 1 person · away **53.8%** · wait 7:24 · S$372/day **B** Fixed, fastest on toppings: 1 person · away **54.2%** · wait 7:28 · S$372/day	
WITH AI INTELLIGENCE forecast-informed roster	**A** 2 people · away **1.2%** · wait 2:38 · S$402/day · +1 staff, −52.6 pts away, +S$30 **B** 2 people · away **4.1%** · wait 4:10 · S$402/day · +1 staff, −50.1 pts away, +S$30	

SPEAKER NOTES · SHARE THE COUNTER

The forecast on 08 set how many people. This slide is how they share the work: same counter, same customers, two sharing rules side by side. The counter is today's split, our scenario, not Chagee's disclosed setup. Robots, the navy boxes, take the order, brew tea and milk, and shake and seal. People do cup and ice, toppings and hand-over.

Left, a bucket brigade: each person carries a cup forward; the last hands it over, walks back and takes over a colleague's cup. Right, fixed stations: each person owns a station.

Press play on an event day. Then set the right side to "slowest on toppings": the queue builds at toppings and customers walk away. The brigade never needed to know who was fast.

Be honest about the other case: add people and fixed stations catch up, or are a little faster. About one minute.

Then click the band to reveal the AI layer on its own. Machines are automation, and here they stay exactly as they are: today's split on both sides. AI means AI-assisted staffing: the demand forecast sets the crew. Equipment, customers and each side's sharing rule are held fixed; only the crew changes. Without AI, the normal-day roster of 1 faces an event day: about 54% of peak-hour orders walk away with a brigade, 54% with fixed posts. With AI, the forecast crew of 2 brings that to 1.2% and 4.1%, for S$402 a day against S$372. The band follows the day you pick. Walk-aways and wait are the peak hour, mean of 20 runs; cost is the day's roster plus machines and leaves out lost sales. All illustrative assumptions.

Course link: the bucket-brigade simulation from Week 5 and Week 6, equipment and technology, inspired this counter replica. Same idea, a different use case.

In our model, one tea-and-milk machine is the cheapest on every day type Pilot this against today's split.

PEAK HOUR

A All by hand 4 people, brigade

minute **20** / 60 served **57** walked away **0** hand-overs **156**

20 runs: away **0.0%** wait **1:25** **S$422**/day

B Machine-made drink (scenario) 2 people, fixed posts

minute **20** / 60 served **57** walked away **0**

20 runs: away **0.0%** wait **1:06** **S$465**/day

Navy = robot, white = by hand (click to switch) · red circle = a person · faded = walking · red cup = waiting for a person.

FIVE OPTIONS, MEAN OF 20 RUNS

EVENT DAY	PEOPLE	WALKED AWAY	WAIT	COST/DAY
Today's split (our scenario)	2	1.2%	2:38	S$402
Machine-made drink (scenario)	2 fixed	0.0%	1:06	S$465
All by hand	4	0.0%	1:25	S$422
All robots	–	0.0%	0:58	S$562
One machine (tea and milk) ✓	**3**	**0.2%**	**1:44**	**S$335**

✓ cheapest within the limit · fastest: All robots

Normal day, cost a day: One machine (tea and milk) S$305 (cheapest) · All by hand S$361 · Today's split (our scenario) S$372 · Machine-made drink (scenario) S$435 · All robots S$562.

Machines = automation, each side's equipment, held fixed. **AI = AI-assisted staffing**: the forecast sets the crew; customers and sharing rule unchanged. Event day · peak hour · mean of 20 runs · illustrative assumptions

WITHOUT AI INTELLIGENCE normal-day roster	**A** All by hand: 2 people · away **40.1%** · wait 5:33 · S$361/day **B** Machine-made drink (scenario): 1 person · away **7.2%** · wait 6:26 · S$435/day	
WITH AI INTELLIGENCE forecast-informed roster	**A** 4 people · away **0.0%** · wait 1:25 · S$422/day · +2 staff, −40.1 pts away, +S$60 **B** 1 person · away **7.2%** · wait 6:26 · S$435/day · the forecast adds no one here	

PROPOSED Pilot one tea-and-milk machine against today's split (our scenario): in our model S$305–335 a day against S$372–402. That holds only while a machine unit costs more than about S$905 a month (same rate for its 1 unit and the split's 3; wage, volume and crews held fixed). We assume S$1,909; Chagee's real cost is unknown.

SPEAKER NOTES · SPLIT THE COUNTER

The forecast set how many people, and the brigade how they share the work; this slide asks which counter steps go to machines. Side A opens on human-only: people do every step. Side B opens on machine-made drink: machines make the drink, people tag the order and hand it over. Both are our illustrative scenarios, not Chagee's disclosed setup. Chagee's own equipment cost is not public; its Singapore relaunch used semi-automated equipment, according to Vulcan Post.

Keep two things apart. Machine automation is the split, the equipment on each side. AI here is AI-assisted staffing: the demand forecast sets the crew. Step four reveals the AI layer on its own. Each side keeps its equipment, customers and sharing rule; only the crew moves from the normal-day roster to the forecast roster. On an event day, all by hand without AI has 2 people, and about 40% of peak-hour orders walk away; with AI the forecast puts on 4, walk-aways fall to 0.0%, median wait 5:32 to 1:24, for S$422 a day against S$361. On the machine-made drink the forecast keeps 1 person, so AI changes nothing there: 7.2% still walk away, and the split table adds a person to meet the limit. In our model, forecasting matters most where people do the work. The band follows the day and the equipment you pick; walk-aways and wait are the peak hour, mean of 20 runs; cost is the day's roster plus machines, without lost sales. Illustrative assumptions throughout.

How to use it: choose a split for each side, or click any station to hand it to a robot or a person, then run the peak hour or press End to compare. Each side starts with the fewest people, from the forecast roster up, that keep walk-aways within 2%.

The table compares five options on the chosen day, mean of 20 runs: today's split, the machine-made drink, all by hand, all robots, and one tea-and-milk machine from the machine ladder in the appendix. In our model, one tea-and-milk machine is the cheapest of the five on every day type, because it lets the roster drop a person off-peak at the cost of one machine unit. All robots is the fastest and the dearest: among these options robots buy a shorter wait, not a lower cost.

Three separate levers, judged one at a time: roster to the forecast, share the work, then let a machine take the fixed steps

PEAK HOUR · BUCKET BRIGADE · EVENT DAY · MEAN OF 20 RUNS

CRITERION	TODAY normal-day roster · today's split	+ FORECAST forecast roster · today's split	+ ONE MACHINE forecast roster · tea-and-milk machine
Crew at the peak	1	2	3
Median wait	7:24	2:38	1:44
Walk-aways	53.8%	1.2%	0.2%
Cups served per person, peak hour	69	74	50
Peak-hour contribution	S$230	S$491	S$482
Cost a day: roster and machines	S$372	S$402	S$335
Walk-aways with fixed posts instead: well / badly assigned	54.2% / 54.2%	4.1% / 34.9%	0.4% / 22.4%

Each column changes one lever from the one before: the forecast changes only the crew; the machine changes only the equipment. The last row swaps the brigade for fixed posts in the same setup. Contribution: peak-hour cups served × price × margin, less the crew's wage for that hour. Illustrative assumptions throughout.

IF THE FORECAST IS OFF · SLIDE 08

On a busy day, a forecast 15% too low puts on 1 person instead of 2: about **21%** walk away. Too high costs about S$15 a day on an event day.

PILOT IN 3 OUTLETS

Shadow the forecast first, then **roster** to it, then run **one machine** against today's split. Compare forecast and actual cups weekly.

MANAGER'S DECISION

Outlet GM · operations manager

For the expected demand, how many people should we roster, how should they share the work, and which steps justify automation?

PROPOSED

Roster to the forecast; test a bucket brigade against fixed posts; pilot one tea-and-milk machine against today's split, which in our model holds while a unit costs more than about S$905 a month (we assume S$1,909; Chagee's cost is unknown).

PROCEED IF, IN THE PILOT

- waits within 5 min and walk-aways within 2% at the peak
- cups per labour hour and operating contribution at least today's
- still true when the forecast is off

NEXT Serving customers better also means being available where demand remains underserved.

SPEAKER NOTES · THE OPERATIONS MANAGER'S DECISION

The decision for part two belongs to the outlet GM or operations manager: for the expected demand, how many people should we roster, how should they share the work, and which steps justify automation?

Read the table left to right; each column changes one lever. First, today: today's split and the normal-day roster. Second, the forecast changes only the crew. Third, a machine changes only the equipment, with the forecast crew. The last row keeps each setup but swaps the bucket brigade for fixed posts, so the sharing rule shows up on its own. That is how we keep forecast-informed staffing, the brigade and machine automation apart.

The criteria are the ones the brief asks for: waiting time, walk-aways, productivity as cups served per person at the peak, and operating contribution. And the forecast will be wrong sometimes: on a busy day a forecast 15% too low lets about 21% walk away, while a forecast too high costs only about S$15 a day on an event day.

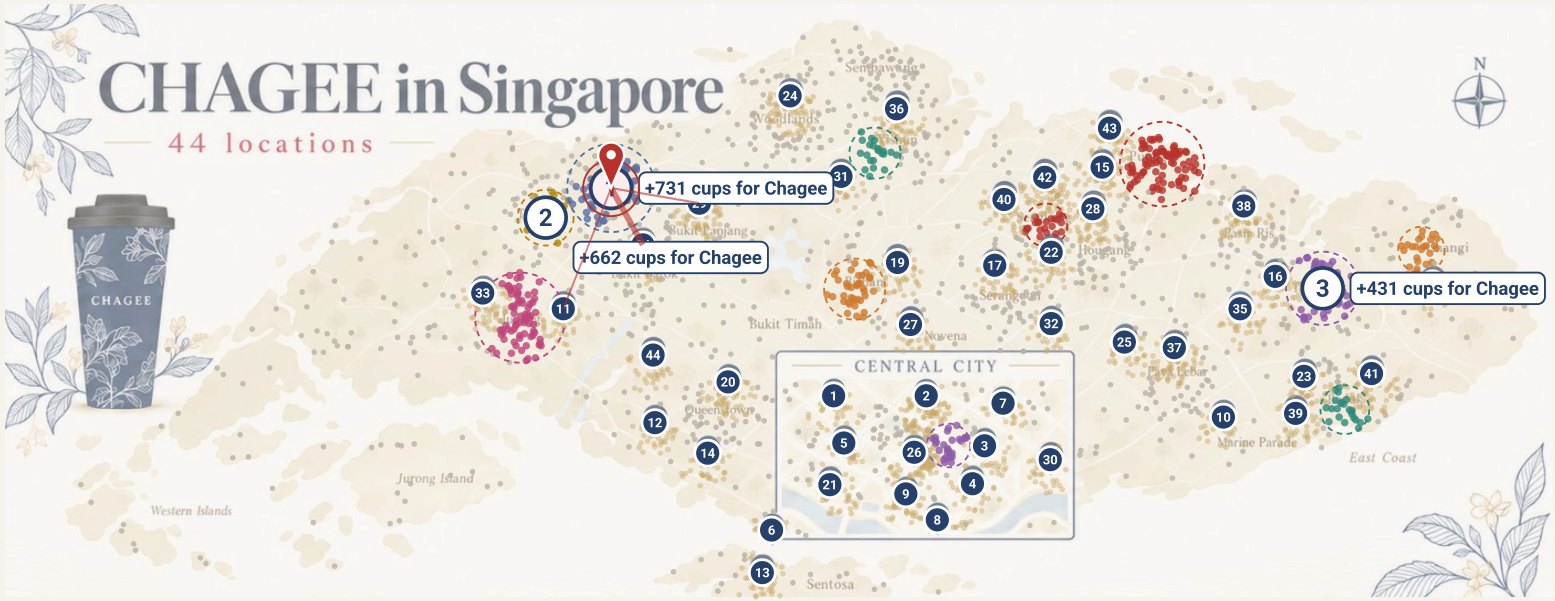

Our proposal: roster to the forecast, test a brigade against fixed posts, and pilot one tea-and-milk machine against today's split in 3 outlets: shadow the forecast first, then roster to it, then the machine. Proceed only if waits, walk-aways, cups per labour hour and contribution hold up, including when the forecast is off. Then the transition: serving customers better also means being available where demand remains underserved. About one minute.

Course link · Week 3 · the Flashion new-store forecast

Where would Outlet #45 add the most cups for Chagee?

BUSINESS PROBLEM A new outlet may look successful while mostly moving sales from nearby stores, while other customers have no convenient outlet. Context Chagee aims to expand rapidly in Singapore; the number of stores is confidential (Chagee source, anonymous). Simulated searches below.

NEW-STORE FORECAST

SUGGESTED SITE 1 · 2.7 KM FROM 34 · WEST MALL

Strong site: mostly new cups

+731 cups a day for Chagee

The new store sells 837 a day (1.5× an average outlet). 106 of those move from outlets nearby:

34 · West Mall, 2.7 km	**−77**
29 · Bukit Panjang Plaza, 3.3 km	**−28**

Peak hour 13:00: **92 cups** → **2 people** on today's counter (slides 08–09).

Synthetic app data on the team's map; outlet positions approximate (the central inset is enlarged). Not a trained model: the point is the method. Its five-year P&L: appendix.

WITHOUT AI our assumed baseline

Open outlet 45 beside 34 · West Mall: it sells **604** cups a day, but 64% are moved from outlets nearby, so **+216** for Chagee.

WITH AI our proposal

DBSCAN clusters synthetic app searches; the assumed demand model scores the same outlet 2.7 km away, near Choa Chu Kang: sells 837, **+731** for Chagee.

SPEAKER NOTES · PREDICT DEMAND FOR A NEW STORE

Part three. Serving customers better also means being available where demand remains underserved. The business problem has two sides: a new outlet can look successful while mostly moving sales from the stores around it, and customers elsewhere may have no convenient outlet at all. Context, from a Chagee source who asked not to be named: Chagee is looking to expand rapidly in Singapore, and how many stores it is going for is confidential. Chagee Singapore runs on its app, with few kiosks. If Chagee logs searches and their location, which we have to confirm, every search is a demand signal, including searches where no store is close. Here the searches are synthetic. That makes the app the forecasting input for a new store, before it has any sales.

Step one: synthetic app sessions on our map. Gold are within walking distance of an outlet; red found no store nearby. Step two: DBSCAN, unsupervised machine learning, groups red searches that are dense; scattered ones are noise. Step three: cluster centres are candidate sites.

Step four: click the map to test a site. The card leads with the gain for Chagee, which is the store's sales minus the cups it takes from nearby outlets, and gives a verdict: strong, mixed, or mostly moving cups. Try a pin next to Tampines West CC: it sells, but most of it moves from the two Tampines outlets nearby. Step five: the forecast's peak hour gives the opening roster for the counter we ran on slides 08 and 09.

If asked how DBSCAN works, press How it works: it replays the algorithm one search at a time on a toy set. The appendix lists every simulated number.

The three sliders are the only inputs: cluster radius, minimum searches per cluster, and how far people will walk. The data is synthetic; with Chagee's real app logs, the same steps would run unchanged. About one and a half minutes.

Judge a site on the customers it adds and the profit it adds, not on what it sells; then look at the downside before any lease

THE SAME NEW OUTLET AT TWO SITES · SYNTHETIC APP DATA · FIVE YEARS, OUR ASSUMPTIONS

CRITERION	BESIDE 34 · WEST MALL OUR ASSUMED BASELINE	CLUSTER NEAR CHOA CHU KANG DBSCAN + DEMAND MODEL
Customer access: cups from people with no outlet within walking distance	47%	**98%**
Cups a day the store sells	604	837
Net additional cups a day, after cups moved from nearby outlets	+216	**+731**
Incremental operating profit, five years, base volume	−S$0.6m	**S$1.9m**
Investment at opening	S$0.4m	S$0.5m incl. AI share
Payback	not within 5 years	about 1.4 years
Downside: low volume, five years	−S$1.2m	S$0.03m, not paid back in 5 years
Upside: high volume, five years	−S$0.2m	S$3.6m

Operating profit before depreciation, interest and tax, after the contribution lost at nearby outlets. Same opening date, equipment and staffing rule at both sites. Every input and year: appendix.

WHAT DBSCAN DOES NOT DO
It finds where unserved searches gather. It does not predict sales or profit: the separate demand model does, on our assumptions, and the searches here are synthetic.

NEW MARKETS, NO APP HISTORY
External area features and explicit demand scenarios stand in, to shortlist pilot locations: a separate extension under Things to consider.

MANAGER'S DECISION
Expansion manager

Which location should we investigate or pilot next, and do its expected incremental returns justify the investment?

PROPOSED
Investigate the cluster near Choa Chu Kang: rerun the method on Chagee's app logs, if searches and location are recorded, before any lease or pilot.

PROCEED IF, ON REAL DATA
- most of its cups come from customers without convenient access
- net additional demand, not moved cups, carries the case
- incremental operating profit covers the investment, with payback and a downside the business accepts

NEXT Our recommendation: three decisions, three owners.

SPEAKER NOTES · THE EXPANSION MANAGER'S DECISION

The decision for part three belongs to the expansion manager: which location should we investigate or pilot next, and do its expected incremental returns justify the investment?

The table puts the same new outlet at two sites and reads down the criteria. Customer access: about 98% of the cluster site's cups come from people with no outlet within walking distance, against 47% beside the existing outlet. Net additional demand: about 731 cups a day against 216. Incremental operating profit over 5 years: about S$1.9m against −S$0.6m, on S$0.5m invested, paying back in about 1.4 years. Then the downside: at low volume the cluster site makes about S$0.03m and does not pay back within 5 years.

Say it plainly: DBSCAN does not predict sales or profit. It finds where unserved searches gather; a separate demand model, on our assumptions, estimates sales and cannibalisation, and the searches are synthetic. So the proposal is to investigate, not to open: rerun the method on Chagee's app logs before any lease. For a new market without app history, external area features and demand scenarios stand in, under Things to consider. About fifty seconds.

Three decisions, three owners: pilot each one, measure it directly, and judge it on its own evidence

A connected business narrative, not one combined model: no simulated benefit is carried from one part to the next, and none are added together.

GROW · CRM MANAGER

Membership and personalisation

PROBLEM

Customers may not find tiering up worth the effort *(informal source, anonymised, to validate)*.

RECOMMEND

Pilot squads, and squads with personalised suggestions, against today's membership, at a reward level the extra orders can pay for.

PROCEED IF

tier progression rises, satisfaction holds, incremental orders reach the break-even (about **0.18** a member a month for squads, **0.20** with AI), and contribution after reward and AI costs is positive.

EVIDENCE

Analytics model and prototype; every number illustrative.

SERVE · OUTLET GM, OPERATIONS MANAGER

In-store operations

PROBLEM

Demand moves by the hour; rosters and fixed posts may not *(queues observed at reopening; walk-aways simulated)*.

RECOMMEND

Roster to the forecast, test a bucket brigade against fixed posts, and pilot one tea-and-milk machine against today's split in 3 outlets.

PROCEED IF

waits, walk-aways, cups per labour hour and operating contribution beat today's, and still hold when the forecast is off.

EVIDENCE

Counter simulation on our assumptions; machine cost unknown.

EXPAND · EXPANSION MANAGER

Store expansion

PROBLEM

A new outlet can mostly move sales from nearby stores, while some customers have no convenient outlet.

RECOMMEND

Investigate the cluster near Choa Chu Kang: rerun on Chagee's app logs, then decide on a pilot.

PROCEED IF

it adds net demand, not just moved cups, and its incremental operating profit covers the investment with an acceptable downside (in our model S$1.9m over 5 years; S$0.03m at low volume).

EVIDENCE

Synthetic app searches; DBSCAN finds clusters, the demand model estimates sales.

TAKEAWAY | Make membership worth joining → serve the demand reliably → open where demand remains underserved.

SPEAKER NOTES · OUR RECOMMENDATION

Our recommendation mirrors the three chapters: three decisions, three owners, and each one is a pilot judged on its own evidence.

For the CRM manager: customers may not find tiering up worth the effort, an informal insight we still have to validate. Pilot squads, and squads with personalised suggestions, against today's membership, at a reward level the extra orders can pay for. Proceed if tier progression rises, satisfaction holds, and the extra orders cover the reward and the AI cost.

For the outlet GM or operations manager: demand moves by the hour, and the roster should too. Roster to the forecast, test a bucket brigade against fixed posts, and pilot one tea-and-milk machine against today's split. Proceed if waits, walk-aways, productivity and contribution beat today's, including when the forecast is wrong.

For the expansion manager: count the cups a new outlet adds, not the ones it sells. Investigate the cluster near Choa Chu Kang on Chagee's real app logs before any lease, and proceed only if its incremental returns justify the investment with an acceptable downside.

One caution to say out loud: these parts connect as a story, but we never add their simulated benefits together or carry membership uplift into the counter or expansion numbers. About forty-five seconds.

THANK YOU

QUESTIONS AND DISCUSSION

OPIM639 · GROUP 3 · KEZIAH, JIN, AYUMI, REVAN

SPEAKER NOTES · THANK YOU

Recap the chain and its owners: the CRM manager makes membership worth joining, the operations manager serves the demand reliably, the expansion manager opens where demand remains underserved. Each part rests on its own assumptions; no simulated uplift is carried from one to the next.

Likely questions: is the brigade always better? No; with spare staff fixed stations are as good. Is the forecast real? No, it is an illustration of the chain, built on stated assumptions.

THINGS TO CONSIDER

EXTENSIONS AND EARLIER WORK, KEPT FOR QUESTIONS AND NEXT STEPS

A NEW MARKET: AUSTRALIA · SITE SCORES AND PIN TO PROFIT · THE DECISIONS IN DETAIL · THE SIZE OF THE BENEFIT

SPEAKER NOTES · THINGS TO CONSIDER

Everything after this slide sits outside the three-part story: extensions and earlier work we can draw on in questions. None of it feeds the main slides' numbers.

 New-market worked example · Australia · scenario assumptions

No Chagee sales history is not the same as no data: profile each area on what a new market can measure

Archetype candidate areas in one Australian state capital, standing in for real suburbs until the data is pulled. We assume Chagee has no operating history there.

CANDIDATE-AREA PROFILES · CONSISTENT FEATURES, EVERY AREA

FEATURE	STANDS IN FOR	A	B	C	D	A REAL VALUE WOULD COME FROM	VALUE HERE
Residents within 1 km	proxy walk-in demand from people living nearby	12k	18k	25k	20k	national census, usual residents by small area	assumption
Workers within 1 km	proxy weekday lunch and after-work demand	90k	20k	12k	5k	census place-of-work counts	assumption
Tertiary students within 1 km	proxy the young, app-first customer base	15k	40k	5k	2k	university and TAFE enrolment by campus	assumption
Household income index	proxy willingness to pay for a premium tea	115	80	95	90	census median household income	assumption
Transit access	proxy footfall past the counter	0.95	0.75	0.70	0.35	public-transport timetable data, services per hour at the nearest stops	assumption
Competitors within 500 m	proxy rival bubble-tea and cafe supply (lowers the score)	9	6	4	2	business listings or a map-places count	assumption
Rent, A$ a month	proxy local cost (lowers the score)	A$22,000	A$12,000	A$10,000	A$8,000	retail lease listings or an agent quote	assumption

Areas (archetypes): A CBD office core · B University precinct · C Suburban rail interchange · D Outer-suburb shopping centre

FOUR KINDS OF INPUT

Sourced observation none yet: no Australian data retrieved for this deck

Proxy what each feature stands in for, such as workers for weekday demand

Scenario assumption every value in the table

Unavailable before opening; left out, below

LEFT OUT · NEEDS CHAGEE ACTIVITY

- **Chagee app searches nearby**: needs Chagee app users in the market
- **Delivery orders from the area**: needs Chagee on the local delivery platforms
- **Distance to the nearest Chagee outlet**: there is none yet
- **Sales of existing Chagee outlets nearby**: there are none yet

Missing is unknown, not zero

No area has app searches or delivery orders yet. Set to zero, they would read as no demand; left out, the areas are compared only on what all of them have.

WHAT IS AI HERE Nothing yet. This is the data step the models on the next slides need; every value stays a scenario assumption until census and market data are pulled.

SPEAKER NOTES · NEW MARKETS: WHAT CAN WE KNOW BEFORE OPENING?

To consider: a new market. The main story was Singapore, where Chagee already trades. Now the harder case: a new market where Chagee has no local operating history. We use Australia as the worked example, and we assume no Chagee history there; that is to confirm.

No sales history does not mean no data. Before opening, a market still has residents, workers, students, income, transport access, competitors and rents. Step one: those are the features, and each is a proxy for something we care about, such as workers for weekday lunch demand. Step two: the same features for every candidate area, so the areas compare like for like.

Step three, be honest about the values. The areas are archetypes, a CBD office core, a university precinct, a suburban rail interchange and an outer-suburb shopping centre, not real suburbs. Every value is a scenario assumption. The table says where a real value would come from, such as the census, but we have not retrieved any Australian data, so there are no sourced observations on this slide yet.

Step four, what we leave out. App searches, delivery orders, distance to the nearest Chagee outlet and the sales of outlets nearby all need Chagee to be trading already. We leave them out rather than set them to zero: zero would read as no demand, when the truth is that we do not know. About forty-five seconds.

New-market worked example · Australia · scenario assumptions

B, A and C can each rank first as the weights move; the score shortlists areas, it does not forecast their sales

SUITABILITY SCORE OUT OF 100 · ILLUSTRATIVE WEIGHTS

B · University precinct rank 1–3 across 15 weightings · first in 6	**52**	cannibalisation 0%
A · CBD office core rank 1–3 across 15 weightings · first in 6	**52**	cannibalisation 0%
C · Suburban rail interchange rank 1–3 across 15 weightings · first in 3	**50**	cannibalisation 0%
D · Outer-suburb shopping centre rank 4 across 15 weightings · first in 0	**32**	cannibalisation 0%

Residents · Workers · Students · Income · Transit · Competitors · Rent · bar = score; rank range across the weight check

DEMAND SCENARIOS, CUPS A DAY · THE SAME FOR EVERY AREA

Low 278 Base 556 High 833

A placeholder scale: our Singapore per-outlet volume assumption, reused. With no calibration from real outlets, the score cannot turn into cups, so every area faces this range.

WEIGHTS USED

Residents 1.00 · Workers 1.00 · Students 1.00 · Income 0.50 · Transit 1.00 · Competitors 0.50 · Rent 0.50. Competitors and rent count against.

WEIGHT CHECK · 15 WEIGHTINGS

Each weight dropped, then doubled, one at a time. **B** first in 6, **A** first in 6, **C** first in 3, **D** first in 0. The top spot is not robust: treat the leaders as a shortlist.

WITH REAL OUTCOMES · SUPERVISED LEARNING

If outlets in existing markets had real sales, with these same features measured around each, a supervised model could learn the weights instead of us choosing them, tested on markets it has not seen. The supervised site model, also under Things to consider, is trained on synthetic Singapore data: **not validated for Australia**, and not used here.

Illustrative. Archetype areas and scenario assumptions: not Australian data, not Chagee data.

SPEAKER NOTES · AUSTRALIA CASE STUDY: WHICH AREAS SHOW POTENTIAL?

Same features, same definitions, every area. Step one: each feature is scaled across the 4 areas from worst to best, competitors and rent count against, and the weights add them up. At our weights the University precinct scores 52, the Outer-suburb shopping centre only 32.

Step two, and this is the point: move the weights. The check re-ranks 15 times, with each weight dropped and then doubled. B, A and C each come first in some of them; the Outer-suburb shopping centre is last in every one. So the score gives a shortlist, not a winner.

Step three: the score does not become a sales forecast. Turning it into cups needs a calibration from real outlets, which we do not have. So every area faces the same low, base and high range, 278, 556 and 833 cups a day, borrowed from our Singapore per-outlet assumption as a placeholder scale.

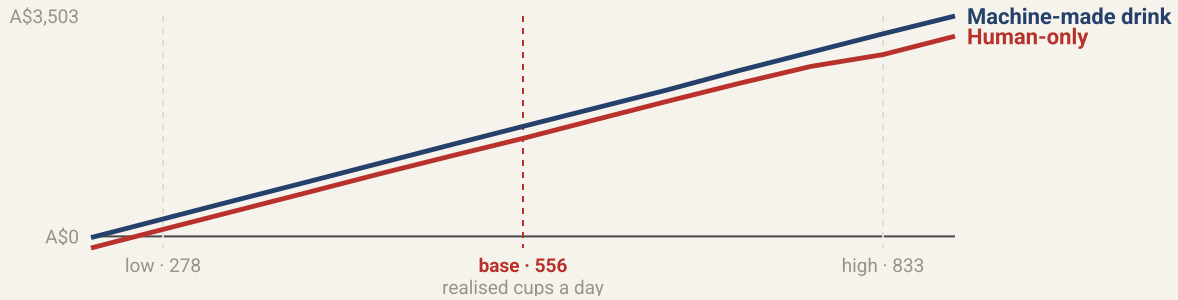

Where supervised learning fits: with real outcomes from outlets in existing markets, a model could learn these weights, tested on markets it has not seen. Our supervised site model is trained on synthetic Singapore data, so it is not validated for Australia, and we do not use it here.

Step four, cannibalisation. For the first opening it is zero: there is no Chagee outlet in any catchment. Switch to the next opening and it appears: an area within 5 km of the pilot loses up to 30% of its cups to it. About one minute.

New-market worked example · Australia · A$ scenario assumptions

With our A$ assumptions, machine-made drink holds up best in the worst case; human-only wins if a machine unit costs more than about A$3,258 a month

OPERATING CONTRIBUTION, A$ A DAY, YEAR AVERAGE · WITH AI STAFFING, EXACT FORECAST

Human-only 268 with AI, 267 without; **Machine-made drink** 236 with AI, 235 without. Normal day, no walk-aways; low scenario 278.

PREFERRED SETUP · WORST CASE

Worst year-average day, any scenario and forecast error: human-only **A$108**, machine-made drink **A$276**. **Machine-made drink** is safer; the two cross at a machine unit of about **A$3,258** a month (now A$2,000); they do not cross within the wage range. With an exact forecast, machine-made drink leads at low, base and high demand.

WITHOUT AI INTELLIGENCE
one crew, all day

Human-only: 2 people · away **40.1%** · wait 5:33 · A$1,766/day
Machine-made drink: 1 person · away **5.4%** · wait 5:51 · A$2,448/day

WITH AI INTELLIGENCE
forecast roster

Human-only (forecast exact): 4 people · away **0.0%** · wait 1:25 · A$2,218/day
· +2 at the peak, +4 staff hours, +A$452
Machine-made drink (forecast exact): 1 person · away **5.4%** · wait 5:51 · A$2,448/day
· same crew: the forecast changes nothing here

SPEAKER NOTES · WHICH OPERATING SETUP WORKS UNDER UNCERTAIN DEMAND?

Now feed the demand scenarios into the same counter simulation as slides 08 and 09, with Australian costs in Australian dollars: a wage of A$36 an hour, A$2,000 a month per machine unit, A$8.5 a cup and A$12,000 a month rent at the University precinct. All scenario assumptions, none sourced. We compare human-only with machine-made drink. Equipment is sized before opening for the base scenario and does not change.

The chart is the year-average operating contribution, before set-up cost, delivery and overheads, as realised demand moves. Machine-made drink is above human-only across the range here, and both are below zero at the low end: break-even is about 236 cups a day for machine-made drink and 268 for human-only, against a low scenario of 278.

Then the AI layer, revealed in the band. Without AI the counter runs one crew all day, set once for a normal day's planned peak. With AI the forecast sets the roster for the day type, but the forecast is not perfect: it can miss realised demand by 30% either way. On an event day at base demand, human-only without AI loses about 40% of peak-hour orders; with an exact forecast, 4 people bring that to 0%, and the day's contribution rises to about A$2,218 from A$1,766. An under-forecast puts on 3 and gives some back: 10% walk away. On machine-made drink the forecast keeps 1 person even on an event day, so 5.4% still walk away: the staffing rule's own capacity estimate is the limit there, not the forecast.

When does the answer change? We judge by the worst case across demand scenarios and forecast errors. Machine-made drink keeps about A$276 a day, human-only A$108. That flips if a machine unit costs more than about A$3,258 a month; across our wage range, A$30 to A$45 an hour, machine-made drink stays ahead. Move the sliders to test it. Walk-aways are counted at the peak-hour rate over the busiest hours only, an approximation. About one and a half minutes.

New-market worked example · Australia · scenario assumptions

Pilot one machine-made drink counter in the University precinct, then let the pilot's own data decide the next step

RECOMMENDATION · CONDITIONAL

Where: the University precinct (B)

First at our weights; B, A and C are the shortlist. No own-store cannibalisation.

Setup: machine-made drink, AI staffing

Best worst case, A$276 a day against A$108 for human-only.

Holds only if

- a machine unit costs under about A$3,258 a month
- volume lands in the placeholder range, 278 to 833 cups a day; break-even is about 236
- the A$ wage, price and rent hold
- the forecast misses by no more than 30%

WHAT THE PILOT MEASURES, AND WHAT IT UPDATES

MEASURE	HOW	UPDATES
Orders, cups a day	till and app records, daily	the placeholder low, base and high range
Hourly demand	order times by hour, by day type	the hourly shape and peak the roster is built on
Conversion, where measurable	store-locator views or footfall against orders	the first link from score to cups
Service times	order to hand-over, per station	station seconds in the counter simulation
Labour needed	crew against waits and walk-aways each hour	the staffing rule and minimum crew
Machine cost and uptime	the lease quote, downtime log	the A$ machine cost and the setup choice

Then rerun: the area ranking with the area's real outcome, the setup comparison with real demand and times. Once several outlets trade, outcomes can train the supervised model; until then, weights stay a judgement.

EVIDENCE TO ACT · HELD 4 WEEKS IN A ROW

Example result, illustrative: 556 cups a day, 0.0% peak walk-aways, a quote of A$2,000.

- **Keep the pilot running.** 556 cups a day against about 236 (machine-made drink, University precinct).
- **No extra staff.** Peak walk-aways 0.0% against the 2% limit.
- **Keep machine-made drink.** Quote A$2,000 against the flip at about A$3,258 a month.
- **Open the next outlet, CBD office core.** It keeps 486 cups after 12.5% cannibalisation, against about 301 to break even.

EXPAND WHEN the pilot clears break-even for 4 weeks in a row, and the next area, the CBD office core, still clears it after losing about 13% of its cups to the pilot. Every figure here is a scenario assumption until the pilot replaces it.

SPEAKER NOTES · PILOT, LEARN, THEN EXPAND

So the answer to where, with what, and what next. Where: the University precinct, first at our weights, with B, A and C as the shortlist. With what: a machine-made drink counter with AI staffing, because it keeps the most in the worst case, about A$276 a day. It is conditional: it holds only while a machine unit costs under about A$3,258 a month, the A$ wage, price and rent hold, and volume lands in our placeholder range. Break-even is about 236 cups a day.

Step two, what the pilot measures: orders and cups a day, demand by hour and day type, conversion where we can measure it, service times per station, the labour each hour actually needs, and the real machine cost and uptime. Step three, how that updates the analysis: real volume replaces the placeholder range, real hourly demand replaces the Singapore shape, service times replace our station seconds, and the area's real outcome is the first calibration from score to cups. Once several outlets trade, those outcomes can train the supervised model.

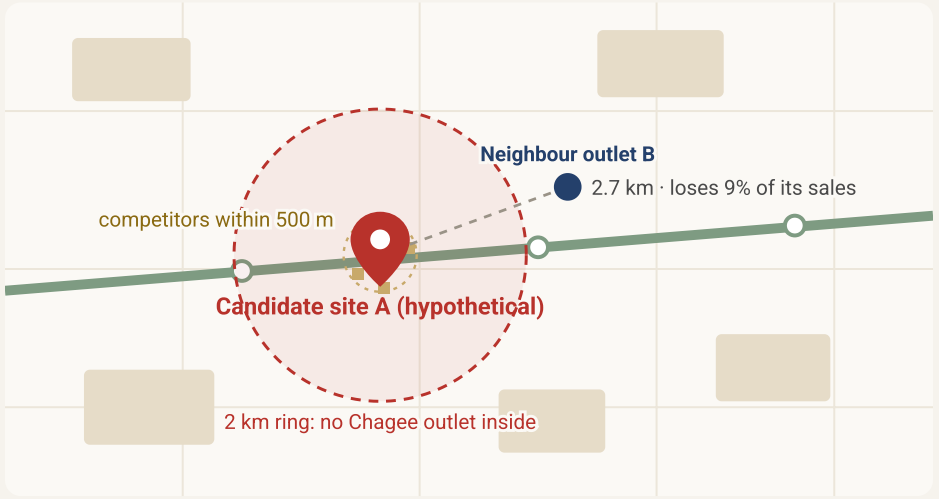

Step four, the evidence to act, each held for 4 weeks in a row. Add staff when peak-hour walk-aways stay above 2% on the forecast roster. Revisit the setup if the firm machine quote is above about A$3,258 a unit a month. Open the next outlet, the CBD office core, only if the pilot clears break-even and the next site still clears it after losing about 13% of its cups to the pilot. Try a pilot result on the right. About one minute.

Extension: where this scales next. Not included in the S$ benefit.

Four scores for every location

Corporate drops a pin; the model rates it on four things (illustrative). Decision owner here: the expansion manager.

SCHEMATIC MAP · HYPOTHETICAL PINS

Demand score HAND-SET — 84
Residents, workers and transit riders within reach, plus footfall.

Delivery demand score HAND-SET — 78
Orders from the area on third-party delivery apps.
All Chagee delivery goes through third-party apps (anonymous Chagee source, to confirm), so we use area demand, not "served from a farther outlet". Whether the platforms share this data is to confirm.

Competition score HAND-SET — 61
Bubble-tea and cafe outlets within 500 m; dense competition lowers the score, a few prove demand.

Cannibalisation factor COMPUTED · SLIDE 10 ENGINE — −13
Site A: 13% of its cups would move from existing Chagee outlets; neighbour outlet B loses 9%. Deducted so the result is net to Chagee.

Site score WEIGHTED — 76
Demand 50%, delivery 20%, competition 30% (hand-set weights).

ATTRIBUTES THE MODEL TAGS TO EACH PIN residents and workers within 1 km · MRT and bus tap-ins · footfall · delivery orders from the area · competing outlets within 500 m · Chagee outlets within 2 km · rent per sq ft · staff needed at peak

WHAT IS AI HERE Scoring a pin from its attributes would be a supervised model trained on outlets' results: a production idea. Here the three scores are set by hand, and the cannibalisation factor is computed by the slide 10 engine on synthetic data. The next slide runs the supervised model.

Illustrative. Synthetic data, not Chagee data. Chagee's opening history is internal and we do not have it.

SPEAKER NOTES · FOUR SCORES FOR EVERY LOCATION

An extension: where this scales next, and not part of the benefit figure. The decision owner here is the expansion manager. This builds on Jin's site-selection framework.

Step through it. Corporate drops a pin; the model tags its attributes; three scores follow. Demand, delivery demand and competition are set by hand here, and you can drag a bar to test another value: in production, a supervised model would score them. We call the second one delivery demand, not delivery relief, because all Chagee delivery runs through third-party apps, according to an anonymous Chagee source; whether the platforms share this data is to confirm.

The cannibalisation factor is computed by the same engine as slide 10: about 13% of site A's cups would move from existing outlets. Switch to the pin with an outlet inside the ring, or the one beside an outlet, and watch it jump. All synthetic. About thirty-five seconds.

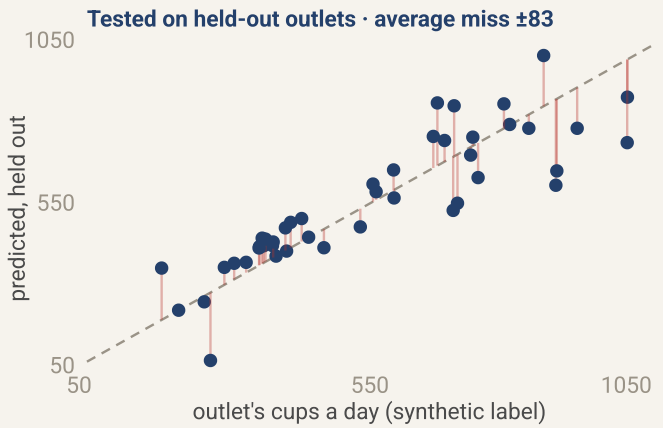

Extension: where this scales next. Not included in the S$ benefit.

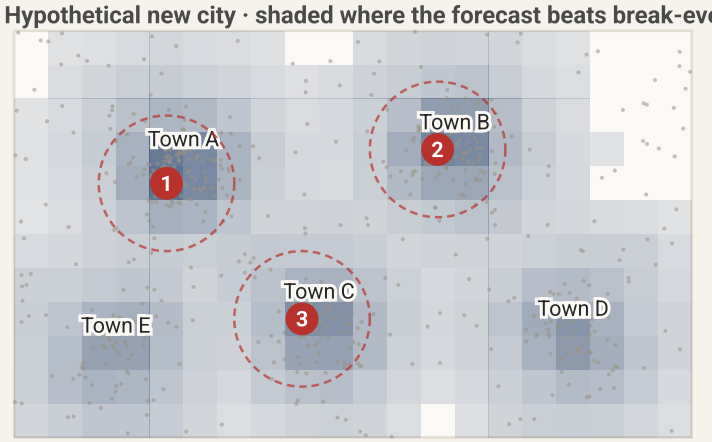

Trained on Singapore's outlets, the model picks where to open in a city where Chagee has no data yet

Supervised learning: keep only the inputs a new city has, test the model on outlets it has not seen, then let it score every spot in a hypothetical city (illustrative, synthetic).

TRAIN ON 44 OUTLETS · TOGGLE THE INPUTS

- ☑ **People within reach** — NEW MARKET: HAS IT
- ☑ **Distance to a town centre** — NEW MARKET: HAS IT
- ☐ Delivery-area demand — NEW MARKET: TO CONFIRM
- ☐ Unserved app searches — NEW MARKET: NONE
- ☐ Chagee outlets nearby — NEW MARKET: NONE
- ☐ Distance to nearest Chagee outlet — NEW MARKET: NONE

TESTED ON OUTLETS IT HAS NOT SEEN

±83 cups a day, average miss

R^2 0.76 with 2 inputs

All inputs (Singapore)	±41 · R^2 0.95
New-market inputs only	±83 · R^2 0.76
No inputs: guess the average outlet	±197

WHERE TO OPEN IN THE NEW CITY

1. Town A: ≈ **1,090** ± 83 · **above break-even even at 1,007** · **beyond what it learned**
2. Town B: ≈ **959** ± 83 · **above break-even even at 876**
3. Town C: ≈ **887** ± 83 · **above break-even even at 804**

Cups a day, forecast ± average miss. Break-even ≈ 275 at Singapore costs (the pin-to-profit slide), a stand-in. Picks ≥ 2 km apart.

WHAT IS AI HERE Supervised learning (ridge regression) from site attributes to cups a day. The labels are the slide 10 engine's synthetic outlets, so the fit flatters; Chagee's real opening history would fit worse. Using Singapore to score another market assumes its customers behave alike: check against the first outlets' actuals.

Illustrative. Synthetic data, not Chagee data. Chagee's opening history is internal and we do not have it.

SPEAKER NOTES · THE SUPERVISED MODEL

This is the model behind step three of the framework, actually running. It learns cups a day from a site's attributes, trained on Singapore's 44 outlets. The labels are synthetic, from the slide 10 engine, so read it as the method, not a forecast.

We test it fairly: each outlet is predicted by a model that never saw it. With every input, it misses by about 41 cups a day on average. Now the proxy for a new market: there is no Chagee app history and no outlet network yet, so switch those inputs off. With only population and distance to a town centre, the error grows to about 83 cups a day, still better than guessing the average outlet, about 197.

Then the point of it: where to open in a place with no local data. The right-hand map is a hypothetical city, generated at the same density as our Singapore data. With only the inputs that city has, the model scores every spot and picks the best sites at least 2 km apart, so they do not take sales from each other. Each pick shows its forecast with the error band, and whether it clears break-even at Singapore costs, which stand in until local costs are known. Picks beyond what the model saw in Singapore are flagged. So the model can travel, but only on inputs the new market has, with wide ranges: pilot the top site first and recheck the model against its actuals. That is the continual-learning step on the next slide. About fifty seconds.

Extension: where this scales next. Not included in the S$ benefit.

From pin to net profit

Six steps from a pin to a go / no-go, on profit net to Chagee overall (illustrative). Decision owner here: the expansion manager.

AI · SIMILARITY SEARCH

5 Forecast net profit
Cups a day, running cost, minus the profit neighbours lose.
COMPUTED BELOW

6 Decide
Open, pilot or skip. Actuals feed back: continual learning.
AI · CONTINUAL LEARNING

NET PROFIT TO CHAGEE, A MONTH · SITE A, TOP APP-SEARCH CLUSTER

At 278–833 cups a day: **−S$3,506** to **S$34,624** a month. Neighbour outlet B, 2.7 km away, loses 9% of its sales. Delivery fees: 30% of cups × 30% commission. Counter: the one-machine setup, normal-day roster (counter model).

STEP 6 · RECOMMENDATION

Pilot

positive at 556 cups a day, negative at 278, the low end: test it before a full lease.

Site score **76 / 100 (four scores)**
Payback **≈ 25 months on S$400,000**

A strong-demand site can still fail if rent or staffing is too high, or if it mostly takes sales from our own neighbours.

In practice this needs Chagee's opening history. With about 44 outlets in Singapore the model must stay simple (few attributes, ranges not point values).

Illustrative. Synthetic data, not Chagee data. Chagee's opening history is internal and we do not have it. Cups a day, price and margin are the benefit slide's; rent, delivery, utilities and set-up cost are assumptions, not Chagee data.

SPEAKER NOTES · FROM PIN TO NET PROFIT

Six steps from a pin to a go or no-go. Steps three, four and six are where the AI would sit in production: a supervised model for the scores, a similarity search for look-alike outlets, and continual learning as each new outlet reports actuals. On this slide only step five is computed.

The waterfall starts from cups a day times price times margin, the same inputs as the benefit slide: 556 cups a day. Take off the profit neighbours lose, delivery fees, the counter, rent and utilities: about S$16,011 a month net to Chagee, a payback of about 25 months. At the low end of the cups range it loses money, so the call is: Pilot. Move rent, delivery or set-up cost and watch the call change; these are our assumptions, not Chagee data.

The honest point: switch to the pin with an outlet 1.7 km away. It takes 44% of its cups from our own outlets and comes out at −S$2,697 a month, a skip. About forty-five seconds.

Later: reuse in new markets via transfer learning, out of scope.

 TBC · DRAFT, TO BE CONFIRMED

Four modelled decisions by owner: where to open for the expansion manager; what to automate, how many people and how to share for the operations manager

	DECISION	WHY, FROM THE MODEL	REVISIT WHEN
1 **Where to open** expansion manager · slide 10 · DBSCAN + assumed demand model	**Open where app searches cluster, not beside an existing outlet.**	**+731** against **+216** cups a day for the same new outlet. Synthetic app-search data: this shows the method, not a finding about real outlets.	Rerun on Chagee's app logs, if searches and location are recorded, before any lease.
2 **What to automate** operations manager · slide 09 · physical AI	**In our model, one tea-and-milk machine is the cheapest on every day type; pilot it against today's split (our scenario).**	**S$305–335** a day against S$372–402. The two cost the same at about **S$905 a month per machine unit** (1 unit against 3), with wage, volume, station speeds and crews held fixed; we assume S$1,909. Amacha's S$10,000 is a one-off price; without machine life, upkeep and financing we cannot turn it into a monthly cost.	When Chagee's real machine cost is known.
3 **How many people** operations manager · slide 08 and the benefit slide · forecast + economic rule	**Economic rule: add a person on event days, not on busy days.**	With the one machine: peak crew 2 → **3** on event days; 2 on busy days, where an extra person costs more than the orders it keeps.	When the forecast peak moves.
4 **How to share** operations manager · slide 08b · operations	**Test a bucket brigade against fixed posts for the hand steps.**	In the recommended setup (one machine, 3 people, event day): **0.2%** walk away with a brigade, 0.4% with well-assigned fixed posts, 22% with badly assigned ones; median wait 1:44 against 2:18.	Fixed posts once there is spare staff.

- **Pilot in 3 outlets**

  Shadow forecast only · **Roster** economic rule · **Machine** one vs today's split

  KPIs: cups per labour hour, wait time and walk-aways at the peak. Compare forecast and actual cups weekly.

- **Limits we know**

  All figures are illustrative assumptions, not Chagee data. Machine costs and speeds are assumed; breakdowns and breaks are not modelled.

- **To confirm with Chagee**

  The real machine cost per unit, whether outlets log wait times and walk-aways, and how today's local staffing calls compare with the forecast.

ASSUMED BASELINE illustrative — One machine and a flat crew of 2 every day: **23%** of event-day peak orders walk away.

PROPOSED SCENARIO in our model — The forecast and the economic rule add a person on event days only (2 → 3): **0.2%** walk away; busy days stay at 2 (0.1%).

SPEAKER NOTES · THE DECISIONS IN DETAIL

TBC: this slide is a draft and still to be confirmed by the team; present it as work in progress.

The detail behind two of the three owners' decisions: four modelled decisions, one per simulation, all on our assumptions. The CRM manager's decision is on slide 07. One, for the expansion manager, where to open: DBSCAN clusters app searches and our assumed demand model scores the sites. The searches are synthetic, so this shows the method; rerun it on Chagee's app logs, if searches and location are recorded, before any lease.

Two to four belong to the outlet GM or operations manager. Two, what to automate: in our model one tea-and-milk machine is the cheapest on every day type, so pilot it against today's split, which is our scenario, not Chagee's disclosed setup. The two cost the same at about S$905 a month per machine unit, comparing one unit against three, with the wage, volume and crews held fixed. We assume S$1,909. We cannot turn the one-off price one small shop paid into a monthly cost without machine life, upkeep and financing, so Chagee's real cost decides this.

Three, how many people: the economic rule adds a person on event days but not on busy days. Four, how to share: test a bucket brigade against fixed posts; in the recommended setup the brigade does a little better than well-assigned fixed posts and much better than badly assigned ones. Then a pilot in 3 outlets: shadow the forecast, roster by the economic rule, and run one machine against today's split, judged on cups per labour hour, wait time and walk-aways. About one minute.

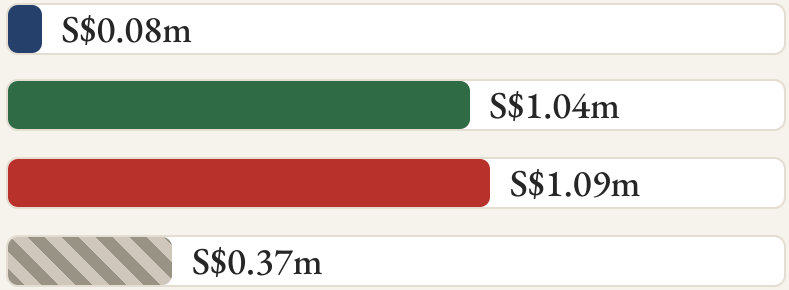

TBC · DRAFT, TO BE CONFIRMED

In our model, about S$1.09m a year across 44 outlets against an illustrative baseline, almost all from one machine's labour saving

Modelled avoided costs on stated assumptions, not demonstrated savings and not savings against Chagee's actual operations, where the GM and teams staff on local expertise. The pilot compares one machine with today's split (our scenario).

PROFIT A YEAR, ALL 44 OUTLETS · ECONOMIC RULE THROUGHOUT

AGAINST THE ILLUSTRATIVE ALL-HAND BASELINE (FLAT NORMAL-DAY ROSTER)

PILOT COMPARISON: THE PROPOSED SCENARIO AGAINST TODAY'S SPLIT (OUR SCENARIO), BOTH ON THE ECONOMIC RULE

Profit = orders kept × price × margin, plus labour saved, minus machine cost. Calendar: 104 busy days (weekends) and 11 event days (public holidays) a year, an illustrative definition. Baseline: all by hand, the normal-day crew every day. Peak hour only, so orders kept are a floor. Every figure, range and both crew rules: appendix.

PHYSICAL AI · ONE TEA-AND-MILK MACHINE

Most of the benefit: labour

Lets the roster drop from 2 people to 1 in the off-peak hours: **S$1.04m** a year after the machine's cost.

FORECAST + ECONOMIC RULE

Adds event-day orders on top of the machine

Adds a person on event days only (2 → 3), keeping about 35 more orders per outlet that day: 390 a year, **S$0.05m** across Singapore. On its own, all by hand: S$0.08m.

READ WITH CARE

The big number rests on one assumption

The minimum crew, 2 by hand and 1 with machines, is ours. Without it, S$1.09m falls to **S$0.37m**. The pilot arm beats today's split by S$1.22m: more than the headline, because today's split is itself S$0.14m below the baseline.

ASSUMED BASELINE illustrative

Flat normal-day roster, all by hand: about **1,291** peak-hour orders a year walk away per outlet.

PROPOSED SCENARIO in our model

Both levers, one run: **1,278** kept a year per outlet, profit **S$1.09m** across 44 outlets (S$0.37m without the minimum-crew rule).

SPEAKER NOTES · THE SIZE OF THE BENEFIT

TBC: this slide is a draft and still to be confirmed by the team; present it as work in progress.

One number and where it comes from, all in our model. Against an illustrative baseline, an all-by-hand counter with the normal-day crew every day, the proposed scenario gives about S$1.09m a year across 44 outlets. That baseline is ours, not Chagee's operations, so these are not savings Chagee would see; they are modelled avoided costs on stated assumptions. Every figure uses the economic rule, the rule the playbook recommends.

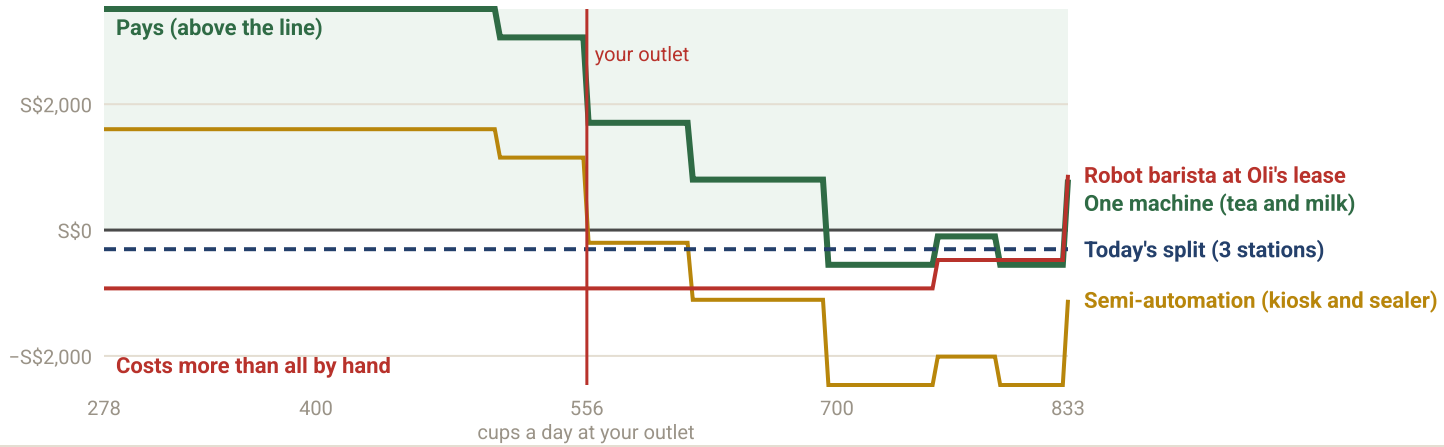

Read the bars. Almost all of it is the one tea-and-milk machine, which lets the roster drop a person off-peak. Rostering to the forecast by the economic rule adds a person on event days only and keeps about 35 more orders per outlet that day, S$0.05m a year across Singapore. The last bar is the pilot comparison: the proposed scenario against today's split, our scenario, both on the economic rule, a difference of S$1.22m.

Say the caveat out loud: the machine's saving comes from our minimum-crew assumption; without it, the total falls to about S$0.37m. Ranges and both crew rules are in the appendix. About one minute.

A machine pays only when it removes a person-shift for less than the shift costs

To our knowledge, based on public sources; vendor list prices, not cost to implement. Chagee's equipment cost is not public; its Singapore relaunch used semi-automated equipment (Vulcan Post).

NET GAIN A MONTH AGAINST ALL BY HAND · ONE OUTLET

Shown at 556 cups a day, wage S$15.06 an hour, S$1,909 a month per machine unit (sliders on screen).

	1 Semi-automation	2 Beverage platform	3 Milk-tea machine	4 Robot arm	5 Robot barista
	Gong Cha Singapore	Gong cha Super Wu	Amacha, one shop	Richtech ADAM	Oli; coffee-first
	Not disclosed	*Not disclosed*	S$10,000 to buy	*Not disclosed, rental only*	US$4,990/mo lease
	PRESS	COMPANY CLAIM	PRESS	VENDOR PAGE	VENDOR PAGE

The model's S$1,909 a month is per station unit (our reading: a semi-automated station). Semi-automation and the beverage platform are priced at it because their real prices are not disclosed; robot prices are per setup. Full table and sources in the appendix.

START HERE

One machine on the tea and milk

+S$1,706 a month vs all by hand

Saves 8 person-hours a day (S$3,614 a month) for one S$1,909 unit. Simple payback, if it lets the roster drop one person-shift: 2.8 months on Amacha's S$10,000.

WATCH

Today's 3-station split

−S$305 a month vs all by hand

Saves 12 person-hours a day (S$5,422) but pays for 3 units (S$5,726).

WAIT FOR VOLUME

Robots: arm or barista

757+ cups a day before they save more labour than today's split (labour only, not a cost break-even)

At 556 cups, Oli's lease (S$6,350) is S$928 a month worse; a robot setup would need to cost under S$5,422 a month. The arm's price is not disclosed.

Model assumption that drives all three: minimum crew 2 by hand, 1 with machines, off-peak. Station speeds are the model's, not vendor claims. Rosters step in whole people, so results flip with volume and wage.

WITHOUT AI
our assumed baseline

All by hand at 556 cups a day: **24 person-hours** a day, **S$10,843** a month of labour.

WITH AI
our proposal

One tea-and-milk machine: **16 person-hours** a day, **+S$1,706** a month after its unit cost. A robot setup (four stations on machines) starts to save more labour than today's split at about 757 cups a day; labour only, not a cost break-even.

SPEAKER NOTES · MACHINE LADDER

Backup for slide 09, for questions on which machine to buy. This is physical AI: automation and machines at the counter. The predictive AI is the forecast that sets the roster. One rule explains the whole slide: a machine pays only when it removes a person-shift, and costs less than that shift.

The chart shows the net gain a month against an all-by-hand counter as volume changes; above the line it pays. One tea-and-milk machine lets the roster drop from 2 people to 1 in 8 off-peak hours, about one person-shift a day, for one station unit: it pays across most of the range. Today's split saves 12 person-hours but pays for 3 units, so it ends up a little dearer than all by hand. A robot setup, four stations on machines, saves no more labour than today's split until about 757 cups a day. That is where extra labour saving begins, not a cost break-even; at Oli's lease it only pays at the top of our range.

Three things to say out loud. The minimum crew, 2 by hand and 1 with machines, is our model's assumption and drives this result. Every option runs at the model's station speeds, not vendor claims. Payback is simple payback, if the machine lets the roster drop one person-shift, with no installation, maintenance or financing. Chagee's own equipment cost is not public. About one minute.

Takeaway: At 556 cups a day: start with one machine (about +S$1,706 a month); today's 3-station split costs S$305 a month more than all by hand; robots save no more labour than today's split until about 757 cups a day.

Per outlet, about 61 orders kept on an event day and 5 on a busy day; on an illustrative calendar, S$7,539 of revenue a year

Modelled avoided costs on stated assumptions, not demonstrated savings, against an illustrative baseline, not Chagee's operations. Economic rule for the headline figures. Peak hour only; conservative. Prices to our knowledge, based on public sources.

Profit a year, 44 outlets: **S$1.09m** = counter automation, physical AI **S$1.04m** (depends on the minimum-crew rule) + forecast roster, predictive AI **S$0.05m** | Without / with the minimum-crew rule: **S$0.37m to S$1.09m**

ONE OUTLET AT 556 CUPS A DAY · BOTH LEVERS, ONE RUN

EVENT DAY
61 orders kept
Revenue S$358 (× S$5.90) · profit S$241
Counter: labour saved − machine S$27

BUSY DAY
5.4 orders kept
Revenue S$32 (× S$5.90) · profit S$76
Counter: labour saved − machine S$57

NORMAL DAY
0.2 orders kept
Revenue S$1 (× S$5.90) · profit S$58
Counter: labour saved − machine S$57

A YEAR	PER OUTLET	44 OUTLETS, IF ALL LOOKED LIKE THIS MODEL
Orders kept peak hour, busy and event days	**1,278** range −121 to 1,452	**56,221**
Revenue orders × price	**S$7,539** range −S$832 to S$10,015	**S$331,704**
Profit margin 50%–70%: −S$754 to +S$754	S$24,660	S$1,085,027
Labour saving, counter labour saved − machine cost; shown on its own	S$20,136	S$886,005

Revenue and labour are never added: revenue is orders × price; profit is orders × price × margin, plus labour saved, minus machine cost.

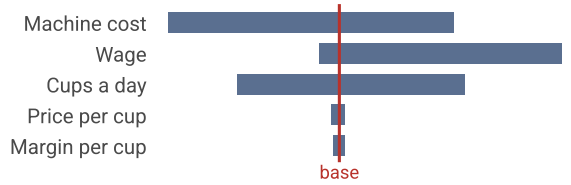

Calendar: 104 busy days (weekend days) and 11 event days (Singapore public holidays) a year: an illustrative definition, to confirm with Chagee; sliders on screen.

Machine	888 · S$23,611	888 · S$23,611
Both, one run	**1,278 · S$24,660**	**1,278 · S$24,660**
Both, today's split counter −S$305/month	1,124 · −S$3,142	1,124 · −S$3,142

Walk-away rule: fewest people keeping peak-hour walk-aways within 2% (the forecast crew at 556 cups a day). Economic rule: add a person only when orders kept × price × margin beat the extra labour. "Both" is one run, not a sum: the levers keep many of the same orders, and with the machine the forecast crew needs fewer extra hours (−S$662 profit against the sum). Headline figures use the economic rule.

Against what
A flat normal-day roster and an all-by-hand counter. Chagee deploys people on local expertise (Chagee source, anonymous), so this baseline is ours, not Chagee's.

All inputs at their worst/best end together
Profit a year, one outlet: low **−S$15,660** · base **S$24,660** · high **S$101,166**

Fragile: the minimum crew
The counter lever rests on the model's minimum crew off-peak: 2 by hand, 1 with machines. Profit a year per outlet: S$24,660 with it; S$8,395 with 1 either way.

Not sized
Delivery levers (third-party; channel margins not disclosed), membership and CRM, waste (no inventory model in this deck), and the new-store site forecast (shown as cups added only).

ASSUMED BASELINE illustrative
Flat normal-day roster, all by hand: about **1,291** peak-hour orders a year walk away per outlet.

PROPOSED SCENARIO in our model
Both levers, one run: **1,278** kept a year per outlet, profit **S$1.09m** across 44 outlets (S$0.37m without the minimum-crew rule).

SPEAKER NOTES · THE BENEFIT IN DETAIL

Backup for the benefit slide. This answers part c of the brief: how big is the benefit, for Singapore only. Against what: a flat normal-day roster and an all-by-hand counter. Chagee deploys people on local expertise, the GM and outlet teams making the calls, so this baseline is ours, not Chagee's practice.

Lead with orders. On an event day the model keeps about 61 orders per outlet in the peak hour that would otherwise walk away, about S$358 of revenue; on a busy day about 5. Over a year it depends on how many such days there are: our illustrative calendar is 104 busy days, the weekends, and 11 event days, the public holidays. That is an input, not a measurement.

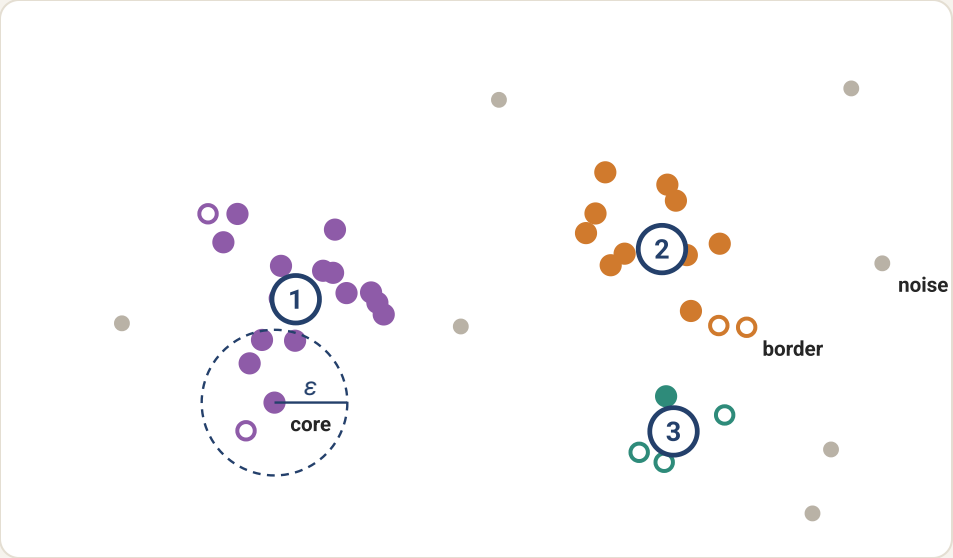

Profit is the second line, using a margin we assume because Chagee does not disclose one. The labour saving is shown separately and never added to revenue. The two levers are run together, not added, because they share the same labour hours. The strip at the top splits the profit: most is counter automation, physical AI, the machine on its own; the forecast, predictive AI, adds a small share on top.

Two crew rules for rostering to the forecast. The walk-away rule adds people until peak-hour walk-aways are within 2%; at our default volume that is exactly the forecast crew. The economic rule adds a person only when the orders kept are worth more than the extra hours. They differ on busy days by hand, where the economic rule adds no one.

Be honest about fragility: most of the profit is the counter's labour saving, and it comes from the model's minimum crew, 2 by hand and 1 with machines. Drop that rule and the profit falls to about S$8,395 a year per outlet. And rostering to the forecast pays on event days, not on busy days, where the extra hours cost more than the orders won back. These are modelled avoided costs on stated assumptions, not demonstrated savings. About one minute.

DBSCAN finds where searches bunch up; a proximity model turns a pin into cups

DBSCAN IN FOUR MOVES · TOY EXAMPLE

1. **Radius ε.** Two searches are neighbours if they are within ε of each other (the cluster-radius slider).
2. **Core.** A search with at least the minimum number of searches within ε (counting itself) is a core point.
3. **Grow.** A cluster spreads from core to core. Searches it reaches that are not core join as border points.
4. **Noise.** Searches no cluster reaches. Unlike k-means, nobody picks the number of clusters, and odd shapes are fine.

Unsupervised: no labels or past openings are needed. Ester, Kriegel, Sander and Xu (1996). On slide 10 it runs only on searches with no outlet within walking distance; each cluster's centre is a candidate site.

THE SIMULATED NUMBERS, IN ORDER · AT THE SLIDER DEFAULTS

1	**App searches**	Synthetic dots on land: 15% spread evenly, 35% around the outlets' malls, the rest around 20 towns	**3,000 dots**
2	**No store nearby**	The nearest outlet is further than the walking distance	**1 km · 46% of dots**
3	**DBSCAN**	Clusters the no-store-nearby dots	**ε 0.6 km · min 15 · 11 clusters**
4	**Pull of a store**	Fades with distance d: exp(−½ (d/L)²), with the length L set by the walking distance	**L = 1 km**
5	**Who buys where**	A dot buys at a store in proportion to its pull, against the pull of not buying (a store next door = one)	**not buying 0.3**
6	**Calibration**	Each dot's weight is set so the average outlet sells the deck's cups a day (cups a year ÷ open days)	**556 cups a day**
7	**Score a pin**	Cups for Chagee = what the new store sells − what it moves from nearby outlets	**top: 837 − 106 = +731**
8	**Verdict**	Share of the new store's cups that are new to Chagee	**strong ≥ 60% · weak < 40%**
9	**Opening roster**	Peak-hour cups ÷ cups one person handles, with the safety margin	**one per 83 cups**

All synthetic: the dots, towns and weights are assumptions on the team's map (not to scale), not Chagee app logs or population data. With real app logs, steps one and two change; the rest runs unchanged.

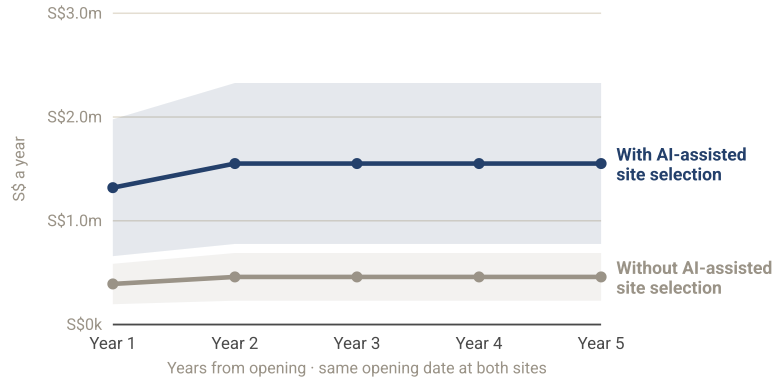

SPEAKER NOTES · HOW THE SITE FORECAST WORKS

Backup for questions on slide 10. Left: DBSCAN in four moves on a toy set. A search is a core point if enough searches sit within the radius; clusters grow from core to core; border points join; the rest is noise. We do not choose the number of clusters.

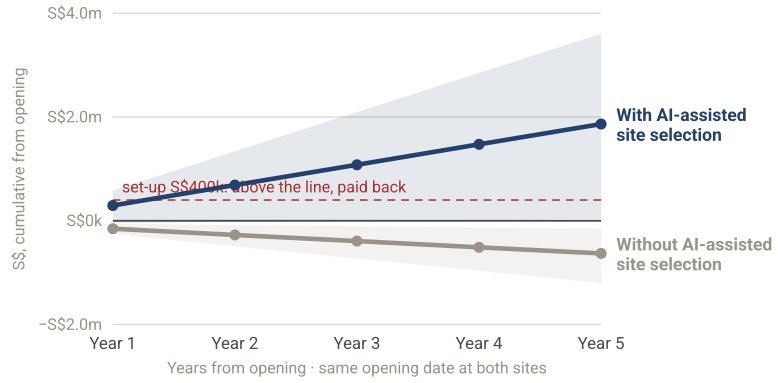

Right: every simulated number, in the order the model uses it. The forecast is only as good as these assumptions; with Chagee's real app logs, the first two rows would be replaced by data and the rest would run as is.

Same new outlet, same opening, same counter: the AI site adds about S$2.5m more operating profit over 5 years, in our model

ANNUAL INCREMENTAL REVENUE TO CHAGEE, S$

CUMULATIVE INCREMENTAL OPERATING PROFIT, S$

THE BRIDGE, FIVE-YEAR TOTALS, BASE SCENARIO

5 YEARS, BASE SCENARIO	WITHOUT AI · +216	WITH AI · +731	DIFFERENCE
New-store sales	S$6.2m	S$8.6m	S$2.4m
− Sales displaced from nearby Chagee outlets	−S$4.0m	−S$1.1m	S$2.9m
= Net additional network sales (incremental revenue)	**S$2.2m**	**S$7.5m**	**S$5.3m**
− New-store ingredients, packaging and delivery commission	−S$3.1m	−S$4.2m	−S$1.2m
− New-store labour (same staffing rule)	−S$325k	−S$412k	−S$87k
− Machines, rent, utilities, maintenance	−S$1.4m	−S$1.4m	S$0k
+ Nearby outlets' variable costs saved (their rent and staff stay)	S$2.0m	S$537k	−S$1.4m
− AI recurring cost (allocated)	S$0k	−S$120k	−S$120k
= Incremental operating profit, before depreciation, interest and tax	**−S$630k**	**S$1.9m**	**S$2.5m**

Illustrative scenarios on our assumptions, not a demonstrated causal gain from AI. DBSCAN finds the search clusters; the assumed demand model estimates the sales. Shaded: the scenario range (our per-outlet volume range), not a confidence interval.

5-YEAR RESULTS · BASE · ILLUSTRATIVE

Revenue uplift	S$5.3m
Operating-profit uplift	S$2.5m
Payback, with AI	1.4 years
Payback, without AI	beyond year 5

Cumulative cash flow after the S$400k set-up (AI site S$460k). AI cost repaid in 2 months. Volume range: S$1.2m to S$3.8m profit uplift.

ASSUMPTIONS · S$ · REUSED UNLESS MARKED NEW

360 days · S$5.90 a cup, held flat · ingredients and packaging 40%
delivery 30% of cups at 30% · wage S$15.06 an hour, same staffing rule
rent S$15,000, utilities S$2,500, maintenance S$800 new a month · same machines
year-one ramp-up 85% new · growth 0.0% new · cost inflation 0.0% new
AI S$60k to build, S$24k a year, 100% on this outlet new · set-up S$400k, outside operating costs

TAKEAWAY

Beside the nearest outlet: **+216** net cups a day → about **S$2.2m** of network sales over 5 years, and **−S$630k** operating profit: the contribution lost at its neighbours outweighs what it makes. With AI-assisted site selection: **+731** net cups a day → about **S$7.5m** and **S$1.9m** after the AI costs: **S$2.5m** more profit than the baseline. Illustrative, not a proven causal gain.

SPEAKER NOTES · THE NEW STORE IN MONEY: FIVE-YEAR P&L

Soft copy and print companion of slide 10's P&L view, at the default inputs and the suggested site. The on-screen view updates with the selected site and the assumption sliders; this page shows the defaults.

Every rung, every price as published, and where it comes from

To our knowledge, based on public sources. Physical AI: automation and machines. A gap is "not disclosed", never a guess.

RUNG	EXAMPLE	AUTOMATES · STEPS ON MACHINES (OUR MAPPING)	VENDOR LIST PRICE	CLAIMS (NOT MODEL INPUTS)	RELIABILITY	SOURCE
1 **Semi-automation**	Gong Cha Singapore	Sugar dispensers, cup sealers, self-order kiosks. **Order and tag, Shake and seal**. Kiosk = order and tag, sealer = shake and seal. Sugar dispensing sits inside tea and milk, so it is not modelled.	*Not disclosed*	Over 20% productivity from self-ordering; 5% manpower saving (no baseline given)	PRESS	https://www.ntuc.org.sg/uportal/news/Technology-Brewing-Up-the-Bubble-Tea-Business/
2 **Beverage platform**	Gong cha Super Wu (Feb 2026)	Dispenses tea, sweeteners and syrups; brewing and shaking stay manual. **Tea and milk**	*Not disclosed*	Up to 65% higher peak productivity	COMPANY CLAIM	https://marketech-apac.com/gong-cha-launches-gong-cha-2-0-to-modernise-global-operations-and-store-design/
3 **Single automated milk-tea machine**	Amacha (one small shop, owner interview)	Makes the milk tea itself. **Tea and milk**	S$10,000 to buy	The shop's total opening cost was S$209,000 (not a machine cost)	PRESS	https://www.malaymail.com/news/life/2026/10/05/opening-a-milk-tea-shop-in-singapore-can-rack-up-to-s209000-even-before-the-first-cup-is-poured/237715
–	**Our scenario: today's split**	**Order and tag, Tea and milk, Shake and seal**. A scenario of ours (slides 08 and 09), not Chagee's disclosed setup	Model: S$1,909 a month per station unit		OUR ASSUMPTION	assumptions.json
4 **Robot arm that makes boba**	Richtech ADAM	Cup, ice, tea, toppings and sealing by one robot arm. **Cup and ice, Tea and milk, Toppings, Shake and seal**	*Not disclosed*. Rental only; price not published	–	VENDOR PAGE	https://richtechrobotics.com/solutions/adam
5 **Robot barista**	Oli	A whole drink station in one unit. **Cup and ice, Tea and milk, Toppings, Shake and seal**. Coffee-first. No tea drinks listed for Oli or Artly.	US$59,000 (≈ S$75,078) to buy; US$4,990 (≈ S$6,350) a month lease	–	VENDOR PAGE	https://olirobotics.com/best-robot-barista
	Artly		US$68,000–88,000 (≈ S$86,530–111,980) to buy; US$2,500–4,000 (≈ S$3,181–5,090) a month lease; US$2,500–4,000 a month software Oli's estimate of a competitor. The figures as given do not say whether the lease replaces or adds to the purchase, so no verdict is computed.	–	VENDOR PAGE	https://olirobotics.com/best-robot-barista
	Cafe X		US$250,000 (≈ S$318,125) to buy Oli's estimate of a competitor's price.	–	VENDOR PAGE	https://olirobotics.com/best-robot-barista
–	**Chagee Singapore**	Chagee's own equipment cost is not public. Its Singapore relaunch used semi-automated equipment.	*Not public*	–	PRESS	https://vulcanpost.com/872176/chagee-singapore-comeback-after-sudden-exit/

Vendor list prices, not cost to implement: installation, training, maintenance, power, space and import are not included; USD converts at S$1.2725 per US$. **Simple payback** = list price ÷ labour saved a month, with no maintenance or financing. **The model's S$1,909 a month** is per station unit: our reading: one semi-automated station unit (for example a dispenser or a cup sealer), amortised with upkeep. Not a robot barista lease; robot prices in machine_tiers.json are per setup. **Vendor speed and throughput claims** are listed, never used: every rung runs at the model's station speeds. **Steps on machines** is our mapping. Artly and Cafe X prices are Oli's estimates of competitors.

SPEAKER NOTES · MACHINE LADDER: TIERS AND SOURCES

Backup for the machine ladder. Every price is as the source publishes it; where a source gives no price we say not disclosed. Claims such as Gong cha's productivity figures are listed for context and are not inputs to our model. Soft copy only.

Where every number comes from

FACTS QUOTED

Outlets in Singapore: 44. Store count used on the storyboard deck. The doc also cites 46 (VnExpress, earlier); the later directory count is used. *[L-sg-directory]*

Global context, group-wide, not Singapore: franchise share of FY2025 net revenue: 0.88. Secondary source; flagged wherever shown. GROUP-WIDE: global context only, never applied to Singapore (Singapore is company-owned, I-sg-owned). *[L-koalagains]*

Global context, group-wide, not Singapore: company-owned share of FY2025 net revenue: 0.12. Secondary source; flagged wherever shown. GROUP-WIDE: global context only, never applied to Singapore (Singapore is company-owned, I-sg-owned). *[L-koalagains]*

Registered members, group-wide, end of June 2026: 257000000. Company statement on the Q2 2026 earnings call (COO, interpreted). Group-wide, not Singapore. Membership is on Chagee's mobile mini program (L-chagee-q1-2025). *[L-chagee-q2-2026-call]*

Orders from members with two or more purchases, group-wide (more than): 0.78. Company statement on the Q2 2026 earnings call. A floor ('more than 78%'). Group-wide, not Singapore. *[L-chagee-q2-2026-call]*

SOURCES

L-sg-directory Chagee Singapore store directory, mapped by the team (44 locations, checked 15 Oct 2026); Mothership, Sep 2026, https://mothership.sg/2026/09/chagee-more-heartland-stores-singapore-eugene-lee/ gives the same count. Taken from the team's ideation doc (OPIM 639_ Ideation Process), not re-checked for this deck.

I-sg-owned PROJECT OWNER CONFIRMATION (23 Oct 2026): Chagee Singapore operates a company-owned model, not a franchise model. Confirmed by the project owner; not from the anonymous Chagee contact and not an external citation. Used on slide 01 (headline, step 1, card, notes). Supersedes the earlier 'ownership not claimed' framing. It does not change the group-wide revenue shares, which stay global context only.

L-koalagains KoalaGains, 'CHA business and moat', https://koalagains.com/stocks/NASDAQ/CHA/business-and-moat (SECONDARY - flag when used): FY2025 net revenue about 88% from the franchise (master franchise) model and about 12% from company-owned stores, the latter growing fastest. Taken from the team's ideation doc (OPIM 639_ Ideation Process), not re-checked for this deck.

L-yfchuhai YF Chuhai, https://www.yfchuhai.com/article/9751.html: Chagee's leaf supply chain is in China; it sources only two ingredients locally, fresh milk and fruit. Taken from the team's ideation doc (OPIM 639_ Ideation Process), not re-checked for this deck.

L-sec20f Chagee Holdings Form 20-F for FY2025, SEC EDGAR, https://www.sec.gov/Archives/edgar/data/2013649/000110465926050766/cha-20251231x20f.htm: separate centralized and regional warehouses to lower storage and logistics costs. Taken from the team's ideation doc (OPIM 639_ Ideation Process), not re-checked for this deck.

L-unsw UNSW BusinessThink, Oct 2024: Chagee semi-automation, baristas scan a QR code and the machine dispenses the formulation. (brief.md section 9)

I-chagee-contact CHAGEE SOURCE, ANONYMOUS (Oct 2026): a Chagee source who asked not to be named; do not identify them. Four points only: whether Singapore outlets are owned, a joint venture or franchised does not matter for this work, because the data sits in one system; Singapore outlets run under one company and one data system; all delivery is via third-party apps; people are deployed on local expertise: the GM and outlet teams make the staffing calls. Ownership itself is not attributed to this source: see I-sg-owned (project owner confirmation).

I-sg-groundfloor INFORMAL - quote in the team's ideation doc (Chagee Singapore's Lee: 'Whenever you see a Chagee, it's always on the first floor'; kiosk-style outlets in basements and MRT stations at entry in 2019). The article is not named in the doc; confirm the source before quoting.

I-team-app-first INFORMAL - team observation in the ideation doc: Chagee Singapore sells mainly through its app, with minimal order kiosks in outlets. Confirm before citing. SUPERSEDED on slide 01 (22 Oct 2026) by P-appstore, P-vulcanpost-comeback and L-sec20f-data; the app's share of orders stays to confirm.

L-ester1996 Ester, M., Kriegel, H.-P., Sander, J. and Xu, X. (1996). A density-based algorithm for discovering clusters in large spatial databases with noise. Proceedings of the Second International Conference on Knowledge Discovery and Data Mining (KDD-96), 226-231. The DBSCAN algorithm used on slide 10.

P-honeycombers PRESS - in-store sightings, indicative. Honeycombers (Feb 2026), https://thehoneycombers.com/singapore/china-bubble-tea-brand-singapore/ : Chagee price sightings in Singapore; not a current full menu.

P-eatbook PRESS - in-store sightings, indicative. Eatbook (Aug 2024), https://eatbook.sg/?p=168476 : Chagee price sightings in Singapore; not a current full menu, and older than the deck.

I-team-expansion INFORMAL - team research (Oct 2026): Chagee is looking to expand rapidly in Singapore; how many stores it is going for is confidential. Singapore only. Confirm before citing.

I-team-site-framework TEAM WORK (Oct 2026): Jin's site-selection framework, two team slides ('Four Scores for Every Location', 'From Pin to Profit Forecast'): four scores per pin, six steps from a pin to a go / no-go on profit net to Chagee. Used for slides 08 and 09 (extension). Its example values and outlet names are not used; ours are illustrative.

L-chagee-q2-2026-call Chagee (CHA) Q2 2026 Earnings Call, full transcript, TradingKey, 29 Aug 2026 (local copy: 'Chagee (CHA) Q2 2026 Earnings Call_ Profit Margin Improves as Overseas GMV Doubles.pdf', supplied by the team). COO's remarks, interpreted: 'As of the end of June, our total registered members reached 257 million. The repurchase rate among active members remain above 43%, while members who made 2 or more purchases accounted for more than 78% of total orders.' Group-wide, not Singapore. The page's AI summary is not used; the quote is from the transcript.

L-chagee-q1-2025 Chagee Holdings, 'Chagee Announces First Quarter 2025 Unaudited Financial Results', GlobeNewswire, 30 May 2025 (local copy supplied by the team; the team's link https://investor.chagee.com/node/6736/pdf blocks automated access, so not checked by us). 'Chagee's Mobile Mini Program had a total of 192.4 million registered members as of March 31, 2025'; active members = registered members who placed an order at least once in a period. Shows that membership sits on Chagee's ordering app. Group-wide.

P-appstore CHAGEE app, App Store listing (team research, Oct 2026; no link supplied, not checked by us): 'Order and pay digitally', 'Order for self-pickup ahead of time', 'Locate our outlets and their operating hours'. The listing seen was the Saudi storefront; its privacy-policy URL includes 'SGMY' (our reading: Singapore and Malaysia, an inference). Privacy label: Precise Location under 'Data Not Linked to You'; search history not listed.

P-vulcanpost-comeback PRESS - Vulcan Post, Jayme Teo, 2 Oct 2024, https://vulcanpost.com/872176/chagee-singapore-comeback-after-sudden-exit/ : after the reopening, with some customers 'waiting for as long as an hour to receive their orders', 'the brand rolled out in-app ordering and delivery and constantly upgraded the ordering process.' Its 'kiosks' are a store format ('pivoting from their takeaway kiosks for comfortable dine-in, sit-down tea bars'), not ordering kiosks. Quotes checked by us, 22 Oct 2026.

L-sec20f-data Chagee Holdings Form 20-F for FY2025 (same filing as L-sec20f), risk factors: 'Our business generates and processes personal, transactional and other data.' and 'we may not be able to use our membership program to deepen our understanding of our target consumers.' No share of orders by app or mini program, and nothing on search or location data, in the parts we read. Quotes checked by us, 22 Oct 2026.

L-sec20f-member Chagee Holdings Form 20-F for FY2025 (same filing as L-sec20f), Item 3.D risk factor 'We may not be successful in expanding our membership and our ability to take advantage of our membership program may be limited.' Both quoted sentences checked word for word by us against the SEC EDGAR filing, 22 Oct 2026.

C-topic8 OPIM639 course slides, Topic 8 (slides08 Service Platforms), slides 30-36: the economy with network effects, r(x) = 1 - x, f(z) = z, equilibria z' and z". Slide 34 quoted word for word, checked by us against the course file, 22 Oct 2026.

I-chagee-contact-tiers Informal source, anonymised, to confirm: a Chagee staff member, paraphrased, not quoted. The barrier to levelling up is not outlet operations; it is whether customers think the effort of tiering up is worth it.

SPEAKER NOTES · SOURCES AND ASSUMPTIONS

Soft copy only.

Every Australian input is a scenario assumption

STATUS

Australia worked example, kept separate from every other section: nothing here feeds the main story (slides 01 to 10) or the benefit and nothing in them is changed. Every Australian input is a scenario assumption; no Australian data has been retrieved for this deck. Archetype areas stand in for real suburbs until Census and market data are pulled. Market status: no local Chagee operating history (assumed for this worked example).

CANDIDATE AREAS (ARCHETYPES, SCENARIO ASSUMPTIONS)

A · CBD office core: residents within 1 km 12, workers within 1 km 90, tertiary students within 1 km 15, household income index 115, transit access 0.95, competitors within 500 m 9, rent, a$ a month 22000

B · University precinct: residents within 1 km 18, workers within 1 km 20, tertiary students within 1 km 40, household income index 80, transit access 0.75, competitors within 500 m 6, rent, a$ a month 12000

C · Suburban rail interchange: residents within 1 km 25, workers within 1 km 12, tertiary students within 1 km 5, household income index 95, transit access 0.7, competitors within 500 m 4, rent, a$ a month 10000

D · Outer-suburb shopping centre: residents within 1 km 20, workers within 1 km 5, tertiary students within 1 km 2, household income index 90, transit access 0.35, competitors within 500 m 2, rent, a$ a month 8000

FEATURES AND WHERE REAL VALUES WOULD COME FROM (NONE RETRIEVED)

Residents within 1 km: stands in for walk-in demand from people living nearby; source to pull: national census, usual residents by small area.

Workers within 1 km: stands in for weekday lunch and after-work demand; source to pull: census place-of-work counts.

Tertiary students within 1 km: stands in for the young, app-first customer base; source to pull: university and TAFE enrolment by campus.

Household income index: stands in for willingness to pay for a premium tea; source to pull: census median household income.

Transit access: stands in for footfall past the counter; source to pull: public-transport timetable data, services per hour at the nearest stops.

Competitors within 500 m: stands in for rival bubble-tea and cafe supply (lowers the score); source to pull: business listings or a map-places count.

Rent, A$ a month: stands in for local cost (lowers the score); source to pull: retail lease listings or an agent quote.

Left out: chagee app searches nearby (needs Chagee app users in the market); delivery orders from the area (needs Chagee on the local delivery platforms); distance to the nearest chagee outlet (there is none yet); sales of existing chagee outlets nearby (there are none yet). They need existing Chagee activity. Missing is unknown, not zero: they are left out, never set to zero, so no area is marked down for a gap every area shares.

INPUTS (ASSUMPTIONS.JSON NEW_MARKET)

weights: residents k 1, workers k 1, students k 1, income index 0.5, transit index 1, competitors 0.5, rent month 0.5 relative weight per feature in the suitability score (0-2) (range 0, 2). Our judgement, illustrative. The new-market ranking slide lets you move each; the sensitivity check re-ranks with each weight set to zero and doubled.

sensitivity: low 0, high 2 multipliers applied to one weight at a time. One-at-a-time sensitivity: each weight times zero (dropped) and times two; the rank range is reported per area.

demand scenarios: store.cups per store per year range and value / store.open days per year cups a day: low, base, high. Placeholder scale only: the Singapore per-outlet volume assumption (itself an assumption, not Chagee data) reused for every Australian area. The score does not set cups: without a calibration from real outlets, every area faces the same range.

forecast error: -0.3, 0, 0.3 share by which the pre-opening forecast misses realised cups a day (range -0.5, 0.5). Scenario assumption: before opening, the forecast cannot know actual demand. Under-forecast, exact, over-forecast.

day mix: moderate 104, large 12 busy and event days a year; the rest of store.open_days_per_year are normal days. Scenario assumption for the Australian pilot: busy days = weekend days; event days = a guess at local public holidays and events, not counted. Weights the year-average contribution on the new-market setup slide.

wage per hour: 36 AUD per hour worked, fully loaded (range 30, 45). Scenario assumption, not sourced. Replace with the applicable award rate plus on-costs before use.

machine cost per unit per month: 2000 AUD per station machine unit per month (range 700, 4000). Scenario assumption, not sourced; the Singapore figure is also an assumption and no exchange rate is applied.

price per cup: 8.5 AUD per cup, in store (range 7, 10). Scenario assumption, not sourced. Check menu prices in the pilot city.

utilities per month: 3000 AUD per outlet per month (range 2000, 4500). Scenario assumption, not sourced.

setups: all hand, heading storyboard.split_presets keys compared. Human-only against machine-made drink, as on slide 09; same station speeds and staffing rule (sim/counter.js).

cannibalisation: overlap km 5, max share 0.3 for a second opening: share of a new outlet's cups taken from the pilot, falling linearly to zero at overlap_km. Scenario assumption. Zero for the first opening: no Chagee outlet is in any catchment.

trigger weeks: 4 consecutive weeks a pilot signal must hold before acting. Our judgement, illustrative.

currency: AUD . Every money figure on the new-market slides and the new-market pilot slide is in Australian dollars (A$). No exchange rate is applied to any Singapore figure.

Reused from the Singapore sections, labelled where used: gross margin per cup (storyboard), the per-outlet volume range (store) as the placeholder demand scale, open hours and days, the hourly demand shape, day-type multipliers, station seconds, staffing rule and minimum crews (sim/counter.js, unchanged).

METHOD (SIM/NEWMARKET.JS)

Score: each feature min-max scaled across the areas (turned round for competitors and rent), weighted mean out of 100. **Sensitivity**: each weight dropped, then doubled, one at a time. **Counter**: equipment sized for the base scenario; realised demand reaches the peak hour as a multiplier on the base arrivals; without AI, one crew all day, set for a normal day's planned peak; with AI, the forecast roster for the day type, the forecast missing realised demand by the stated error. **Contribution**: served cups x price x margin, less labour, machine units, rent and utilities, a day; the peak-hour walk-away share is applied to the busiest hours, other hours assumed served. **Worst case**: the lowest year-average contribution over demand scenarios and forecast errors, with AI staffing.

CLAIMS WE DID NOT MAKE

No Australian data and no Chagee data are used. The areas are archetypes, not suburbs. The score is not a sales forecast; the supervised site model is not validated for Australia. No figure on the new-market slides feeds the main story or the benefit.

SPEAKER NOTES · NEW MARKET: INPUTS AND METHOD

Soft copy only. Backup for the new-market slides: every new-market input, how the numbers are worked out, and what we do not claim.

From one customer's rule to the tipping point, and how far a friend network moves it

DERIVATION (OPIM639 TOPIC 8, SLIDES 30 TO 36)

Customer x in (0, 1) has interest r(x) = 1 - x. With a share z of friends participating, x joins if r(x) k z >= p, that is x <= 1 - p/(k z): the share who would join is 1 - p/(k z). An equilibrium is a share that reproduces itself, z = 1 - p/(k z), which gives **p = k z (1 - z)**. This hump is the equilibrium curve of the population; one customer's benefit is r k z, a straight line in z.

The hump peaks at k/4, at z = 50%. If p < k/4 the effort line crosses it twice: **z' = (1 - sqrt(1 - 4p/k))/2**, the unstable tipping point, and **z" = (1 + sqrt(1 - 4p/k))/2**, the stable level. At p = k/4 they merge at 50%; above it there is no positive equilibrium and participation falls to zero from any start. Rounds: z_next = max(0, min(1, 1 - p/(k z))).

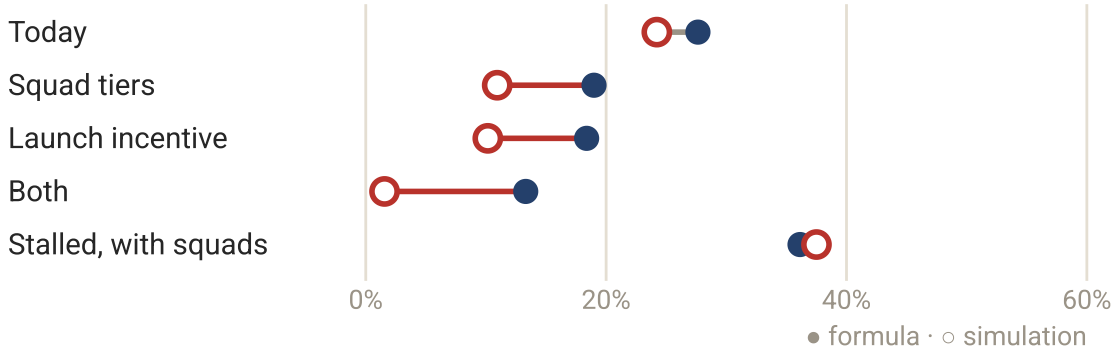

PARAMETERS (ILLUSTRATIVE INDEX, NOT CHAGEE DATA)

r individual interest, 0 to 1, uniform across customers. **k** value of friends participating; squads are hypothesised to raise it. **z** share of a customer's friends participating. **p** effort score of joining or progressing, 0 to 1: 1 is the whole benefit a fully interested customer gets with every friend on at k = 1; not money. Slider defaults: p 0.2, k 1, incentive 0, z0 0.35. Levers, read from the scenario table: squads add 0.3 to k; a launch incentive takes 0.05 off p.

SCENARIO TABLE, COMPUTED (SIM/MEMBERS.JS); THE BUILD FAILS IF IT DIFFERS FROM MEMBERS.EXPECTED_TABLE

Scenario	p	k	4p/k	z'	z"
Today	0.20	1.0	0.80	28%	72%
Squad tiers	0.20	1.3	0.62	19%	81%
Launch incentive	0.15	1.0	0.60	18%	82%
Both	0.15	1.3	0.46	13%	87%
Stalled app	0.30	1.0	1.20	none	none
Stalled, with squads	0.30	1.3	0.92	36%	64%

NETWORK CHECK · CLOSED FORM AGAINST THE FRIEND-NETWORK SIMULATION

Scenario	Closed form z'	Simulated	Gap, points
Today	28%	24%	-3.4
Squad tiers	19%	11%	-8.1
Launch incentive	18%	10%	-8.2
Both	13%	2%	-11.7
Stalled app	none	none	
Stalled, with squads	36%	38%	+1.4

2,000 customers on a seeded random graph with about 8 friends each, interest uniform; a customer is on next round if r k (share of friends on) >= p. 20 seeded runs; the simulated tipping point is the smallest starting share (to 0.01) from which the mean run ends above 10%. Gaps above five points mean the friend-group structure matters: with a handful of friends each, pockets of friends keep each other on, so the network tips lower than the formula, which assumes everyone sees the whole population's share. We report the gap, not hide it.

SPEAKER NOTES · MEMBERS: THE MODEL AND ITS CHECKS

The break-even across the margin range, every new input, and what the sources say

BREAK-EVEN OF THE GROUP-ORDER CREDIT

Contribution per member a month = price x (margin x E - credit x (B + E)), with E extra orders and B group orders a member would place anyway. Break-even E* = credit x B / (margin - credit); none if the credit reaches the margin. Price S$5.90, credit 5%, B 2, E 1.

Gross margin	Extra orders needed a month	With AI cost (slide 07)	Contribution a member a month at E
50%	0.22	0.24	S$2.06
60%	0.18	0.20	S$2.65
70%	0.15	0.17	S$3.24

With personalised suggestions (slide 07) a flat AI cost a of S$0.05 a member a month is added: E* = (credit x B + a / price) / (margin - credit). Personalisation must add a / (price x (margin - credit)) = 0.02 orders a month on top of squads alone at the base margin.

NEW INPUTS (ASSUMPTIONS.JSON MEMBERS; ASSUMPTION, NOT CHAGEE DATA)

group credit share: 0.05 (range 0, 0.1). New input, assumption, not Chagee data.

extra orders per member month: 1 (range 0, 3). New input, assumption, not Chagee data.

base group orders per member month: 2 (range 0, 6). Invented for the break-even (the credit is paid on orders that would have happened anyway); assumption, not Chagee data.

ai cost per member month: 0.05 (range 0, 0.3). Illustrative placeholder, not sourced: the running cost of personalised suggestions per participating member, allocated. Replace with a quoted cost before any decision. Used only on slide 07 to show what personalisation must add on top of squads.

squad size: 2, 6. Our proposal, a design choice, not a Chagee feature claim.

example interest: 0.5. Display only: a middling customer, to separate one customer's benefit from the equilibrium curve.

app rules: points own drink 10, points per squad drink 5, points now 220, points next 300, tier now Silver, tier next Gold, people Mei, Jun, Aisha, Ravi, squad name Lunch squad, prefs Mei usual Jasmine milk tea · 50% sugar, suggest Oolong milk tea · 50% sugar, why you often pick floral teas at lunch and rated an oolong highly, Jun usual Black milk tea · less ice, suggest Black milk tea · 25% sugar, why you switched to less sugar in your last few orders, gift options Black milk tea · 25% sugar, Oolong milk tea · less ice, Fresh fruit tea, Aisha usual Fresh fruit tea, suggest Jasmine milk tea · no ice, why you liked jasmine teas when ordering for yourself, Ravi usual Oolong milk tea, suggest Oolong milk tea · less sugar, why close to your usual, with the sugar level you picked last week. Our illustrative rules for the proposed experience, used consistently on slide 06. Not Chagee's membership rules, which are to confirm. The group-order credit is members.group_credit_share. Preferences and suggestions are illustrative data, not learned from anyone. Recalling the last order is the baseline; the proposed AI part ranks alternatives from each member's own choices, acceptances and dismissals. No real messages, purchases or accounts.

network: customers 2000, friends per customer 8, runs 20, max rounds 200, z0 step 0.01, takeoff share 0.1. Assumption: eight friends each, a squad plus a few more. The closed form assumes everyone sees the whole population's share; a friend group sees a noisy sample of it. Assumption, not Chagee data

SOURCE EXCERPTS · QUOTED WORD FOR WORD

> "we cannot accurately predict the rate or range of consumers who will join our membership program"
>
> Chagee Form 20-F, FY 2025, Item 3.D, risk factors

> "we may not be able to use our membership program to deepen our understanding of our target consumers"
>
> Chagee Form 20-F, FY 2025, Item 3.D, same risk factor

> "The value z′ is the hump the firm must get over in order to succeed."
>
> OPIM639, Topic 8, Service Platforms, slide 34

INFORMAL SOURCE, ANONYMISED, TO CONFIRM

Paraphrased, not quoted: the barrier to levelling up is not outlet operations; it is whether customers think the effort of tiering up is worth it.

How the enhanced forecast is built, and how it compares on synthetic windows

WHAT THIS IS

A synthetic demonstration of the mechanics only: one outlet's peak half-hour pickup window, with squad signals generated by our assumptions. The enhanced forecast can only help to the extent we assume the signals carry information, so this shows how the forecast would work, not measured accuracy. Nothing here feeds any other slide.

THE FORECASTS

Baseline: the calendar expectation for the window, cups a day x the peak hour's share x half an hour. **Enhanced**: the baseline's non-squad part, plus cups confirmed so far, plus predicted cups not yet confirmed: open baskets' unconfirmed invitees x the chance learned from synthetic history that they still confirm by then, unredeemed gifts x the learned chance of redemption, and the squad cups history says arrive from baskets and gifts not yet started. Each forecast uses only signals up to its time; a confirmed cup is counted once; an invitation or an unredeemed gift is never a confirmed drink.

MEAN ABSOLUTE ERROR, CUPS, OVER 400 SYNTHETIC WINDOWS

Squad share	120 min before: baseline / enhanced	60 min before: baseline / enhanced	30 min before: baseline / enhanced	10 min before: baseline / enhanced
0%	6.75 / 6.75	6.75 / 6.75	6.75 / 6.75	6.75 / 6.75
15%	6.86 / 6.83	6.86 / 6.28	6.86 / 6.16	6.86 / 5.95
30%	7.29 / 7.23	7.29 / 6.11	7.29 / 5.65	7.29 / 5.31
45%	7.79 / 7.70	7.79 / 6.13	7.79 / 5.19	7.79 / 4.63

With no squad share the two are identical. The enhanced forecast improves only because the synthetic squad signals were generated to move with demand; on single days it can be worse, when walk-in demand moves and squads cannot see it. Not measured accuracy.

SIGNALS AND WHERE THEY STAND

Documented: completed purchases (Chagee's Form 20-F: the business generates personal, transactional and other data; L-sec20f-data); in-app ordering at a chosen outlet (Vulcan Post, P-vulcanpost-comeback; App Store listing, P-appstore, not checked by us). **To confirm**: drink customisations and the pickup time chosen, in Chagee's Singapore app. **Proposed, needing collection and consent**: group size and confirmed quantities, suggestion accepted, edited or dismissed, gifts sent and redeemed, open baskets and invitations.

INPUTS (ASSUMPTIONS.JSON SQUADCAST; ASSUMPTION, SYNTHETIC, NOT CHAGEE DATA)

window minutes: 30 minutes in the pickup window. The window is the peak hour's first half (store.hourly_demand_share), so its calendar baseline is the deck's own volume: cups a day x the peak hour's share / 2.

lead minutes: 120 minutes before the window that the playback starts. Display and simulation horizon.

social share: 0.3 share of the window's cups that come through squad group orders and gifts, on average (range 0, 0.5). Hypothesis to test; zero means no squad signals, and the enhanced forecast then equals the baseline.

invites per basket: 4 people invited to a group basket, on average (squad size 2 to 6) (range 2, 6). Illustrative.

member conversion: 0.75 share of invited members who confirm a drink (range 0.3, 1). Illustrative; the forecast does not know it and estimates it from synthetic history.

confirm delay minutes: 8 average minutes from a basket opening to a member confirming. Illustrative.

gifts per window: 1.5 gifts sent for this window, on average, at the default squad share (scales with the squad share). Illustrative.

gift redeem share: 0.6 share of gifts redeemed for this window. Illustrative; an unredeemed gift is never counted as a drink.

gift redeem delay minutes: 30 average minutes from sending a gift to its redemption. Illustrative.

day shock sd: 0.2 spread of the day's demand around the calendar baseline (both walk-in and squad cups move with it). Illustrative: why the calendar baseline misses on any one day.

history windows: 400 past synthetic windows the enhanced forecast learns its conversion and late-arrival rates from. Synthetic history, same generator, different seeds.

eval windows: 400 synthetic windows used to compare the two forecasts (appendix). Different seeds from the history.

eval leads: 120, 60, 30, 10 minutes before the window at which the forecasts are compared. Appendix table.

day picks: 0.8, 1, 1.25 actual cups against the calendar baseline for the three example days on the slide (quiet, typical, busy). Display: the example days are the seeds whose actual cups, as a share of the baseline, are closest to these.

drink mix: Jasmine milk tea 0.35, Oolong milk tea 0.3, Black milk tea 0.2, Fresh fruit tea 0.15 share of cups by drink, for predicted cups not yet chosen. Illustrative generic drinks, not Chagee's menu or sales mix.

Course link: OPIM639 Topic 1, slide 12 (capture demand data, not just sales data) and slide 13 (personalised service); Topic 2, slide 17 (the operator that provides fulfilment holds the detailed data). C-topic1, C-topic2.

SPEAKER NOTES · GROUP ORDERS TO FORECASTS: METHOD AND RESULTS
